27 June 2004

The 6502 Firmware Page

This site is mostly about the firmware -- software in ROM -- that came with the original Apple II, not the II+, IIe, IIC, or IIgs. The original Apple II had 4K of RAM and 8K of ROM. The ROM contains software, such as the Monitor and Integer BASIC, appropriate for a SBC.

Red Book refers to the original Apple II Reference Manual dated 1978.

WOZPAK refers to the WOZPAK II, a publication by Call-A.P.P.L.E., an Apple II user group.

DDJ refers to Dr. Dobbs Journal, a computer magazine.

IA refers to Interface Age, a publication of the SCCS (Southern California Computer Society).

SYM and AIM refer to early 6502 single board computers.

Contents

- * Apple II ROM (12 KB binary)
- * Memory map of the Apple II ROMs
- * Summary of Monitor Commands
- * Red Book Monitor listing
- * Red Book Sweet-16 listing
- * WOZPAK Sweet-16 article by Steve Wozniak
- * WOZPAK Sweet-16 article by Dick Sedgewick
- * Red Book Mini-Assembler listing
- * Red Book Floating point listing
- * WOZPAK Floating point routines description
- * DDJ Floating point article
- * IA Floating point article
- * SYM Monitor listing
- * AIM Monitor listing
- * AIM BASIC Language Reference Manual

+-----+
```

Memory map of the Apple II ROMs

- * \$F800-\$FFFF

Monitor. Handles screen I/O and keyboard input. Also has a disassembler, memory dump, memory move, memory compare, step and trace functions, lo-res graphics routines, multiply and divide routines, and more. This monitor has the cleanest code of all the Apple II monitors. Every one after this had to patch the monitor to add functions while still remaining (mostly) compatible. Complete source code is in the manual.

- \$F689-F7FC

Sweet-16 interpreter. Sweet-16 code has been benchmarked to be about half the size of pure 6502 code but 5-8 times slower. The renumber routine in the Programmer's Aid #1 is written in Sweet-16, where small size was much more important than speed. Complete source code is in the manual.

- \$F500-F63C and \$F666-F668

Mini-assembler. This lets you type in assembly code, one line at a time, and it will assemble the proper bytes. No labels or equates are supported--it is a MINI assembler. Complete source code is in the manual.

- \$F425-F4FB and \$F63D-F65D

Floating point routines. Woz's first plans for his 6502 BASIC included floating point, but he abandoned them when he realized he could finish faster by going integer only. He put these routines in the ROMs but they are not called from anywhere. Complete source code is in the manual.

- \$E000-F424

Integer BASIC by Woz (Steve Wozniak, creator of the Apple II). "That BASIC, which we shipped with the first Apple II's, was never assembled--ever. There was one handwritten copy, all handwritten, all hand assembled." Woz, October 1984.

- \$D800-DFFF

Empty ROM socket. There was at least one third party ROM add-on.

- \$D000-D7FF

Programmer's Aid #1--missing from the original Apple II, this is a ROM add-on Apple sold that contains Integer BASIC utilities such as high-resolution graphics support, renumber, append, tape verify, music, and a RAM test. Complete source code is in the manual.

```

|  TOPIC -- Apple II -- Summary of Monitor Commands
+-----+
```

Summary of Apple II Monitor Commands

Examining Memory.

* {adrs}

Examines the value contained in one location.

* {adrs1}. {adrs2}

Displays the values contained in all locations between {adrs1} and {adrs2}.

* [RETURN]

Displays the values in up to eight locations following the last opened location.

Changing the Contents of Memory.

* {adrs}: {val} {val} ...

Stores the values in consecutive memory locations starting at {adrs}.

* : {val} {val}

Stores values in memory starting at the next changeable location.

Moving and Comparing.

* {dest}<{start}. {end} M

Copies the values in the range {start}. {end} into the range beginning at {dest}. (M=move)

* {dest}<{start}. {end} V

Compares the values in the range {start}. {end} to those in the range beginning at {dest}. (V=verify)

Saving and Loading via Cassette Tape.

* {start}. {end} W

Writes the values in the memory range {start}. {end} onto tape, preceded by a ten-second leader.

* {start}. {end} R

Reads values from tape, storing them in memory beginning at {start} and stopping at {end}. Prints "ERR" if an error occurs.

Running and Listing Programs.

* {adrs} G

Transfers control to the machine language program beginning at {adrs}. (G=go)

* {adrs} L

Disassembles and displays 20 instructions, starting at {adrs}. Subsequent L's will display 20 more instructions each. (L=list)

Miscellaneous.

* {adrs} S

Disassembles, displays, and execute the instruction at {adrs}, and display the contents of the 6502's internal registers. Subsequent S's will display and execute successive instructions. (S=step)

* {adr\$}T
Step infinitely. The TRACE command stops only when it executes a BRK instruction or when you press RESET. (T=trace)

* Contrl -E
Displays the contents of the 6502's registers. (E=examine)

* I
Set Inverse display mode.

* N
Set Normal display mode. Also useful as a delimiter for putting multiple commands on one line.

* Control -B
Enter the language currently installed in the Apple's ROM (cold start at \$E000).

* Control -C
Reenter the language currently installed in the Apple's ROM (warm start at \$E003).

* {val 1}+{val 2}
Add the two values and print the result.

* {val 2}-{val 1}
Subtract the second value from the first and print the result.

* {slot} Control -P
Divert output to the device whose interface card is in slot number {slot}. If {slot}=0, then route output to the Apple's screen.

* {slot} Control -K
Accept input from the device whose interface card is in slot number {slot}. If {slot}=0, then accept input from the Apple's keyboard.

* Control -Y
Jump to the machine language subroutine at location \$03F8. This lets you add your own commands to the Monitor.

The Mini - Assembler.

* F666G
Invoke the Mini - Assembler.

* \${command}
Execute a Monitor command from the Mini - Assembler.

* FF69G
Leave the Mini - Assembler.

SWEET 16: A Pseudo 16 Bit Microprocessor

by Steve Wozniak

Description:

While writing APPLE BASIC for a 6502 microprocessor, I repeatedly encountered a variant of MURPHY'S LAW. Briefly stated, any routine operating on 16-bit data will require at least twice the code that it should. Programs making extensive use of 16-bit pointers (such as compilers, editors, and assemblers) are included in this category. In my case, even the addition of a few double-byte instructions to the 6502 would have only slightly alleviated the problem. What I really needed was a 6502/RCA 1800 hybrid - an abundance of 16-bit registers and excellent pointer capability. My solution was to implement a non-existent (meta) 16-bit processor in software, interpreter style, which I call SWEET 16.

SWEET 16 is based on sixteen 16-bit registers (R0-15), which are actually 32 memory locations. R0 doubles as the SWEET 16 accumulator (ACC), R15 as the program counter (PC), and R14 as the status register. R13 holds compare instruction results and R12 is the subroutine return stack pointer if SWEET 16 subroutines are used. All other SWEET 16 registers are at the user's unrestricted disposal.

SWEET 16 instructions fall into register and non-register categories. The register ops specify one of the sixteen registers to be used as either a data element or a pointer to data in memory, depending on the specific instruction. For example INR R5 uses R5 as data and ST @R7 uses R7 as a pointer to data in memory. Except for the SET instruction, register ops take one byte of code each. The non-register ops are primarily 6502 style branches with the second byte specifying a +/-127 byte displacement relative to the address of the following instruction. Providing that the prior register op result meets a specified branch condition, the displacement is added to the SWEET 16 PC, effecting a branch.

SWEET 16 is intended as a 6502 enhancement package, not a stand alone processor. A 6502 program switches to SWEET 16 mode with a subroutine call and subsequent code is interpreted as SWEET 16 instructions. The nonregister op RTN returns the user program to 6502 mode after restoring the internal register contents (A, X, Y, P, and S). The following example illustrates how to use SWEET 16.

300 B9 00 02	LDA	I N, Y	; get a char
303 C9 CD	CMP	#"M"	; "M" for move
305 D0 09	BNE	NOMOVE	; No. Skip move
307 20 89 F6	JSR	SW16	; Yes, call SWEET 16

30A 41	MLOOP	LD	@R1	; R1 holds source
30B 52		ST	@R2	; R2 holds dest. addr.
30C F3		DCR	R3	; Decr. length
30D 07 FB		BNZ	MLoop	; Loop until done
30F 00		RTN		; Return to 6502 mode.
310 C9 C5	NOMOVE	CMP	#"E"	; "E" char?
312 D0 13		BEQ	EXIT	; Yes, exit
314 C8		I NY		; No, cont.

NOTE: Registers A, X, Y, P, and S are not disturbed by SWEET 16.

Instruction Descriptions:

The SWEET 16 opcode listing is short and uncomplicated. Excepting relative branch displacements, hand assembly is trivial. All register opcodes are formed by combining two Hex digits, one for the opcode and one to specify a register. For example, opcodes 15 and 45 both specify register R5 while codes 23, 27, and 29 are all ST ops. Most register ops are assigned in complementary pairs to facilitate remembering them. Therefore, LD and ST are opcodes 2N and 3N respectively, while LD @ and ST @ are codes 4N and 5N.

Opcodes 0 to C (Hex) are assigned to the thirteen non-register ops. Except for RTN (opcode 0), BK (0A), and RS (0B), the non register ops are 6502 style branches. The second byte of a branch instruction contains a +/- 127 byte displacement value (in two's complement form) relative to the address of the instruction immediately following the branch.

If a specified branch condition is met by the prior register op result, the displacement is added to the PC effecting a branch. Except for the BR (Branch always) and BS (Branch to a Subroutine), the branch opcodes are assigned in complementary pairs, rendering them easily remembered for hand coding. For example, Branch if Plus and Branch if Minus are opcodes 4 and 5 while Branch if Zero and Branch if NonZero are opcodes 6 and 7.

SWEET 16 Opcode Summary:

Register OPS-

1n	SET	Rn	Constant (Set)
2n	LD	Rn	(Load)
3n	ST	Rn	(Store)
4n	LD	@Rn	(Load Indirect)
5n	ST	@Rn	(Store Indirect)
6n	LDI	@Rn	(Load Double Indirect)
7n	STDI	@Rn	(Store Double Indirect)
8n	POP	@Rn	(Pop Indirect)
9n	STP	@Rn	(Store POP Indirect)
An	ADD	Rn	(Add)
Bn	SUB	Rn	(Sub)
Cn	POPD	@Rn	(Pop Double Indirect)
Dn	CPR	Rn	(Compare)

En	I NR	Rn	(Increment)
Fn	DCR	Rn	(Decrement)

Non-register OPS-

00	RTN		(Return to 6502 mode)
01	BR	ea	(Branch always)
02	BNC	ea	(Branch if No Carry)
03	BC	ea	(Branch if Carry)
04	BP	ea	(Branch if Plus)
05	BM	ea	(Branch if Minus)
06	BZ	ea	(Branch if Zero)
07	BNZ	ea	(Branch if NonZero)
08	BM1	ea	(Branch if Minus 1)
09	BNM1	ea	(Branch if Not Minus 1)
0A	BK		(Break)
0B	RS		(Return from Subroutine)
0C	BS	ea	(Branch to Subroutine)
0D			(Unassigned)
0E			(Unassigned)
0F			(Unassigned)

Register Instructions:

SET:

SET Rn, Constant [1n Low High]

The 2-byte constant is loaded into Rn (n=0 to F, Hex) and branch conditions set accordingly. The carry is cleared.

EXAMPLE:

15 34 A0 SET R5 \$A034 ; R5 now contains \$A034

LOAD:

LD Rn [2n]

The ACC (R0) is loaded from Rn and branch conditions set according to the data transferred. The carry is cleared and contents of Rn are not disturbed.

EXAMPLE:

15 34 A0 SET R5 \$A034
25 LD R5 ; ACC now contains \$A034

STORE:

ST Rn [3n]

The ACC is stored into Rn and branch conditions set according to the data transferred. The carry is cleared and the ACC contents are not disturbed.

EXAMPLE:

```
25      LD   R5      ; Copy the contents  
36      ST   R6      ; of R5 to R6
```

LOAD INDIRECT RECT:

```
LD @Rn      [ 4n ]
```

The low-order ACC byte is loaded from the memory location whose address resides in Rn and the high-order ACC byte is cleared. Branch conditions reflect the final ACC contents which will always be positive and never minus 1. The carry is cleared. After the transfer, Rn is incremented by 1.

EXAMPLE

```
15 34 A0  SET R5 $A034  
45      LD   @R5      ; ACC is loaded from memory  
                    ; location $A034  
                    ; R5 is incr to $A035
```

STORE INDIRECT RECT:

```
ST @Rn      [ 5n ]
```

The low-order ACC byte is stored into the memory location whose address resides in Rn. Branch conditions reflect the 2-byte ACC contents. The carry is cleared. After the transfer Rn is incremented by 1.

EXAMPLE:

```
15 34 A0  SET R5 $A034      ; Load pointers R5, R6 with  
16 22 90  SET R6 $9022      ; $A034 and $9022  
45      LD   @R5      ; Move byte from $A034 to $9022  
56      ST   @R6      ; Both ptrs are incremented
```

LOAD DOUBLE-BYTE INDIRECT RECT:

```
LDD @Rn      [ 6n ]
```

The low order ACC byte is loaded from memory location whose address resides in Rn, and Rn is then incremented by 1. The high order ACC byte is loaded from the memory location whose address resides in the incremented Rn, and Rn is again incremented by 1. Branch conditions reflect the final ACC contents. The carry is cleared.

EXAMPLE:

```
15 34 A0  SET R5 $A034      ; The low-order ACC byte is loaded  
65      LDD @R6      ; from $A034, high-order from  
                    ; $A035, R5 is incr to $A036
```

STORE DOUBLE-BYTE INDIRECT RECT:

STD @Rn [7n]

The low-order ACC byte is stored into memory location whose address resides in Rn, and Rn is incremented by 1. The high-order ACC byte is stored into the memory location whose address resides in the incremented Rn, and Rn is again incremented by 1. Branch conditions reflect the ACC contents which are not disturbed. The carry is cleared.

EXAMPLE:

```
15 34 A0 SET R5 $A034 ; Load pointers R5, R6
16 22 90 SET R6 $9022 ; with $A034 and $9022
65 LDD @R5 ; Move double byte from
76 STD @R6 ; $A034-35 to $9022-23.
; Both pointers incremented by 2.
```

POP INDIRECT RECT:

POP @Rn [8n]

The low-order ACC byte is loaded from the memory location whose address resides in Rn after Rn is decremented by 1, and the high order ACC byte is cleared. Branch conditions reflect the final 2-byte ACC contents which will always be positive and never minus one. The carry is cleared. Because Rn is decremented prior to loading the ACC, single byte stacks may be implemented with the ST @Rn and POP @Rn ops (Rn is the stack pointer).

EXAMPLE:

```
15 34 A0 SET R5 $A034 ; Init stack pointer
10 04 00 SET R0 4 ; Load 4 into ACC
55 ST @R5 ; Push 4 onto stack
10 05 00 SET R0 5 ; Load 5 into ACC
55 ST @R5 ; Push 5 onto stack
10 06 00 SET R0 6 ; Load 6 into ACC
55 ST @R5 ; Push 6 onto stack
85 POP @R5 ; Pop 6 off stack into ACC
85 POP @R5 ; Pop 5 off stack
85 POP @R5 ; Pop 4 off stack
```

STORE POP INDIRECT RECT:

STP @Rn [9n]

The low-order ACC byte is stored into the memory location whose address resides in Rn after Rn is decremented by 1. Branch conditions will reflect the 2-byte ACC contents which are not modified. STP @Rn and POP @Rn are used together to move data blocks beginning at the greatest address and working down. Additionally, single-byte stacks may be implemented with the STP @Rn ops.

EXAMPLE:

```
14 34 A0 SET R4 $A034 ; Init pointers
15 22 90 SET R5 $9022
84 POP @R4 ; Move byte from
95 STP @R5 ; $A033 to $9021
84 POP @R4 ; Move byte from
95 STP @R5 ; $A032 to $9020
```

ADD:

ADD Rn [An]

The contents of Rn are added to the contents of ACC (R0), and the low-order 16 bits of the sum restored in ACC. the 17th sum bit becomes the carry and the other branch conditions reflect the final ACC contents.

EXAMPLE:

```
10 34 76 SET R0 $7634 ; Init R0 (ACC) and R1
11 27 42 SET R1 $4227
A1 ADD R1 ; Add R1 (sum=B85B, C clear)
AO ADD R0 ; Double ACC (R0) to $70B6
; with carry set.
```

SUBTRACT:

SUB Rn [Bn]

The contents of Rn are subtracted from the ACC contents by performing a two's complement addition:

$$\text{ACC} = \text{ACC} + \text{Rn} + 1$$

The low order 16 bits of the subtraction are restored in the ACC, the 17th sum bit becomes the carry and other branch conditions reflect the final ACC contents. If the 16-bit unsigned ACC contents are greater than or equal to the 16-bit unsigned Rn contents, then the carry is set, otherwise it is cleared. Rn is not disturbed.

EXAMPLE:

```
10 34 76 SET R0 $7634 ; Init R0 (ACC)
11 27 42 SET R1 $4227 ; and R1
B1 SUB R1 ; subtract R1
; (diff=$340D with c set)
B0 SUB R0 ; clears ACC. (R0)
```

POP DOUBLE-BYTE INDIRECT:

POPD @Rn [Cn]

Rn is decremented by 1 and the high-order ACC byte is loaded

from the memory location whose address now resides in Rn. Rn is again decremented by 1 and the low-order ACC byte is loaded from the corresponding memory location. Branch conditions reflect the final ACC contents. The carry is cleared. Because Rn is decremented prior to loading each of the ACC halves, double-byte stacks may be implemented with the STD @Rn and POPD @Rn ops (Rn is the stack pointer).

EXAMPLE:

```
15 34 A0    SET   R5    $A034      ; Init stack pointer
10 12 AA    SET   R0    $AA12      ; Load $AA12 into ACC
75          STD   @R5      ; Push $AA12 onto stack
10 34 BB    SET   R0    $BB34      ; Load $BB34 into ACC
75          STD   @R5      ; Push $BB34 onto stack
C5          POPD  @R5      ; Pop $BB34 off stack
C5          POPD  @R5      ; Pop $AA12 off stack
```

COMPARE:

CPR Rn [Dn]

The ACC (R0) contents are compared to Rn by performing the 16 bit binary subtraction ACC-Rn and storing the low order 16 difference bits in R13 for subsequent branch tests. If the 16 bit unsigned ACC contents are greater than or equal to the 16 bit unsigned Rn contents, then the carry is set, otherwise it is cleared. No other registers, including ACC and Rn, are disturbed.

EXAMPLE:

```
15 34 A0          SET   R5    $A034      ; Pointer to memory
16 BF A0          SET   R6    $A0BF      ; Limit address
B0               LOOP1 SUB   R0          ; Zero data
75               STD   @R5      ; Clear 2 locations
                  ; increment R5 by 2
25               LD    R5          ; Compare pointer R5
D6               CPR   R6          ; to limit R6
02 FA             BNC   LOOP1      ; loop if C clear
```

INCREMENT:

INR Rn [En]

The contents of Rn are incremented by 1. The carry is cleared and other branch conditions reflect the incremented value.

EXAMPLE:

```
15 34 A0    SET   R5    $A034      ; (Pointer)
B0          SUB   R0          ; Zero to R0
55          ST    @R5      ; Clr Location $A034
E5          INR   R5          ; Incr R5 to $A036
55          ST    @R5      ; Clrs location $A036
                  ; (not $A035)
```

DECREMENT:

DCR Rn [Fn]

The contents of Rn are decremented by 1. The carry is cleared and other branch conditions reflect the decremented value.

EXAMPLE: (Clear 9 bytes beginning at location A034)

15 34 A0	SET R5 \$A034	; Init pointer
14 09 00	SET R4 9	; Init counter
B0	SUB R0	; Zero ACC
55	LOOP2 ST @R5	; Clear a mem byte
F4	DCR R4	; Decrement count
07 FC	BNZ LOOP2	; Loop until Zero

Non-Register Instructions:

RETURN TO 6502 MODE:

RTN 00

Control is returned to the 6502 and program execution continues at the location immediately following the RTN instruction. The 6502 registers and status conditions are restored to their original contents (prior to entering SWEET 16 mode).

BRANCH ALWAYS:

BR ea [01 d]

An effective address (ea) is calculated by adding the signed displacement byte (d) to the PC. The PC contains the address of the instruction immediately following the BR, or the address of the BR op plus 2. The displacement is a signed two's complement value from -128 to +127. Branch conditions are not changed.

NOTE: The effective address calculation is identical to that for 6502 relative branches. The Hex add & Subtract features of the APPLE][monitor may be used to calculate displacements.

d = \$80 ea = PC + 2 - 128
d = \$81 ea = PC + 2 - 127

d = \$FF ea = PC + 2 - 1
d = \$00 ea = PC + 2 + 0
d = \$01 ea = PC + 2 + 1

d = \$7E ea = PC + 2 + 126
d = \$7F ea = PC + 2 + 127

EXAMPLE:

\$300: 01 50 BR \$352

BRANCH IF NO CARRY:

BNC ea [02 d]

A branch to the effective address is taken only if the carry is clear, otherwise execution resumes as normal with the next instruction. Branch conditions are not changed.

BRANCH IF CARRY SET:

BC ea [03 d]

A branch is effected only if the carry is set. Branch conditions are not changed.

BRANCH IF PLUS:

BP ea [04 d]

A branch is effected only if the prior 'result' (or most recently transferred data) was positive. Branch conditions are not changed.

EXAMPLE: (Clear mem from A034 to A03F)

15 34 A0	SET R5 \$A034	; Init pointer
14 3F A0	SET R4 \$A03F	; Init limit
B0	LOOP3 SUB R0	
55	ST @R5	; Clear mem byte
		; Increment R5
24	LD R4	; Compare limit
D5	CPR R5	; to pointer
04 FA	BP LOOP3	; Loop until done

BRANCH IF MINUS:

BM ea [05 d]

A branch is effected only if prior 'result' was minus (negative, MSB = 1). Branch conditions are not changed.

BRANCH IF ZERO:

BZ ea [06 d]

A Branch is effected only if the prior 'result' was zero. Branch conditions are not changed.

BRANCH IF NONZERO

BNZ ea [07 d]

A branch is effected only if the prior 'result' was non-zero. Branch conditions are not changed.

BRANCH IF MINUS ONE

BM1 ea [08 d]

A branch is effected only if the prior 'result' was minus one (\$FFFF Hex). Branch conditions are not changed.

BRANCH IF NOT MINUS ONE

BNM1 ea [09 d]

A branch effected only if the prior 'result' was not minus 1. Branch conditions are not changed.

BREAK:

BK [0A]

A 6502 BRK (break) instruction is executed. SWEET 16 may be re-entered non destructively at SW16d after correcting the stack pointer to its value prior to executing the BRK.

RETURN FROM SWEET 16 SUBROUTINE:

RS [0B]

RS terminates execution of a SWEET 16 subroutine and returns to the SWEET 16 calling program which resumes execution (in SWEET 16 mode). R12, which is the SWEET 16 subroutine return stack pointer, is decremented twice. Branch conditions are not changed.

BRANCH TO SWEET 16 SUBROUTINE:

BS ea [0c d]

A branch to the effective address (PC + 2 + d) is taken and execution is resumed in SWEET 16 mode. The current PC is pushed onto a SWEET 16 subroutine return address stack whose pointer is R12, and R12 is incremented by 2. The carry is cleared and branch conditions set to indicate the current ACC contents.

EXAMPLE: (Calling a 'memory move' subroutine to move A034-A03B to 3000-3007)

15 34 A0	SET R5 \$A034	; Init pointer 1
14 3B A0	SET R4 \$A03B	; Init limit 1
16 00 30	SET R6 \$3000	; Init pointer 2
0C 15	BS MOVE	; Call move subroutine
45	MOVE LD @R5	; Move one
56	ST @R6	; byte
24	LD R4	
D5	CPR R5	; Test if done
04 FA	BP MOVE	
OB	RS	; Return

Theory of Operation:

SWEET 16 execution mode begins with a subroutine call to SW16. All 6502 registers are saved at this time, to be restored when a SWEET 16 RTN instruction returns control to the 6502. If you can tolerate indefinite 6502 register contents upon exit, approximately 30 usec may be saved by entering at SW16 + 3. Because this might cause an inadvertant switch from Hex to Decimal mode, it is advisable to enter at SW16 the first time through.

After saving the 6502 registers, SWEET 16 initializes its PC (R15) with the subroutine return address off the 6502 stack. SWEET 16's PC points to the location preceding the next instruction to be executed. Following the subroutine call are 1-, 2-, and 3-byte SWEET 16 instructions, stored in ascending memory like 6502 instructions. The main loop at SW16B repeatedly calls the 'execute instruction' routine to execute it.

Subroutine SW16C increments the PC (R15) and fetches the next opcode, which is either a register op of the form OP REG with OP between 1 and 15 or a non-register op of the form 0 OP with OP between 0 and 13. Assuming a register op, the register specification is doubled to account for the 3 byte SWEET 16 registers and placed in the X-reg for indexing. Then the instruction type is determined. Register ops place the doubled register specification in the high order byte of R14 indicating the 'prior result register' to subsequent branch instructions. Non-register ops treat the register specification (right-hand half-byte) as their opcode, increment the SWEET 16 PC to point at the displacement byte of branch instructions, load the A-reg with the 'prior result register' index for branch condition testing, and clear the Y-reg.

When is an RTS really a JSR?

Each instruction type has a corresponding subroutine. The subroutine entry points are stored in a table which is directly indexed into by the opcode. By assigning all the entries to a common page, only a single byte to address need be stored per routine. The 6502 indirect jump might have been used as follows to transfer control to the appropriate subroutine.

LDA	#ADRH	; High-order byte.
STA	IND+1	
LDA	OPTBL, X	; Low-order byte.
STA	IND	
JMP	(IND)	

To save code, the subroutine entry address (minus 1) is pushed onto the stack, high-order byte first. A 6502 RTS (return from subroutine) is used to pop the address off the stack and into the 6502 PC (after incrementing by 1). The net result is that the desired subroutine is reached by executing a subroutine return instruction!

Opcode Subroutines:

The register op routines make use of the 6502 'zero page indexed by X' and 'indexed by X direct' addressing modes to access the specified registers and indirect data. The 'result' of most register ops is left in the specified register and can be sensed by subsequent branch instructions, since the register specification is saved in the high-order byte of R14. This specification is changed to indicate R0 (ACC) for ADD and SUB instructions and R13 for the CPR (compare) instruction.

Normally the high-order R14 byte holds the 'prior result register' index times 2 to account for the 2-byte SWEET 16 registers and the LSB is zero. If ADD, SUB, or CPR instructions generate carries, then this index is incremented, setting the LSB.

The SET instruction increments the PC twice, picking up data bytes in the specified register. In accordance with 6502 convention, the low-order data byte precedes the high-order byte.

Most SWEET 16 non-register ops are relative branches. The corresponding subroutines determine whether or not the 'prior result' meets the specified branch condition and if so, update the SWEET 16 PC by adding the displacement value (-128 to +127 bytes).

The RTN op restores the 6502 register contents, pops the subroutine return stack and jumps indirect through the SWEET 16 PC. This transfers control to the 6502 at the instruction immediately following the RTN instruction.

The BK op actually executes a 6502 break instruction (BRK), transferring control to the interrupt handler.

Any number of subroutine levels may be implemented within SWEET 16 code via the BS (Branch to Subroutine) and RS (Return from Subroutine) instructions. The user must initialize and otherwise not disturb R12 if the SWEET 16 subroutine capability is used since it is utilized as the automatic return stack pointer.

Memory Allocation:

The only storage that must be allocated for SWEET 16 variables are 32 consecutive locations in page zero for the SWEET 16 registers, four locations to save the 6502 register contents, and a few levels of the 6502 subroutine return address stack. If you don't need to preserve the 6502 register contents, delete the SAVE and RESTORE subroutines and the corresponding subroutine calls. This will free the four page zero locations ASAV, XSAV, YSAV, and PSAV.

User Modifications:

You may wish to add some of your own instructions to this implementation of SWEET 16. If you use the unassigned opcodes \$0E and \$0F, remember that SWEET 16 treats these as 2-byte instructions. You may wish to handle the break instruction as a SWEET 16 call, saving two bytes of code each time you transfer into SWEET 16 mode. Or you may wish to use the SWEET 16 BK (break) op as a 'CHAROUT' call in the interrupt handler. You can perform absolute jumps within SWEET 16 by loading the ACC (R0) with the address you wish to jump to (minus 1) and executing a ST R15 instruction.

| TOPIC -- Apple II -- WOZPAK Sweet-16 article by Dick Sedgewick
+-----

SWEET 16 - INTRODUCTION

by Dick Sedgewick

Sweet 16 is probably the least used and least understood seed in the Apple][.

In exactly the same sense that Integer and Applesoft Basics are languages, SWEET 16 is a language. Compared to the Basics, however, it would be classed as low level with a strong likeness to conventional 6502 Assembly language.

To use SWEET 16, you must learn the language - and to quote "WOZ", "The opcode list is short and uncomplicated". "WOZ" (Steve Wozniak), of course is Mr. Apple, and the creator of SWEET 16.

SWEET 16 is ROM based in every Apple][from \$F689 to \$F7FC. It has its own set of opcodes and instruction sets, and uses the SAVE and RESTORE routines from the Apple Monitor to preserve the 6502 registers when in use, allowing SWEET 16 to be used as a subroutine.

It uses the first 32 locations on zero page to set up its 16 double byte registers, and is therefore not compatible with Applesoft Basic without some additional efforts.

The original article, "SWEET 16: The 6502 Dream Machine", first appeared in Byte Magazine, November 1977 and later in the original "WOZ PAK". The article is included here and again as test material to help understand the use and implementation of SWEET 16.

Examples of the use of SWEET 16 are found in the Programmer's Aid #1, in the Renumber, Append, and Relocate programs. The Programmer's Aid Operating Manual contains complete source assembly listings, indexed on page 65.

The demonstration program is written to be introductory and simple, consisting of three parts:

1. Integer Basic Program
2. Machine Language Subroutine
3. SWEET 16 Subroutine

The task of the program will be to move data. Parameters of the move will be entered in the Integer Basic Program.

The "CALL 768" (\$300) at line 120, enters a 6502 machine language subroutine having the single purpose of entering SWEET 16 and subsequently returning to BASIC (addresses \$300,

\$301, \$302, and \$312 respectively). The SWEET 16 subroutine of course performs the move, and is entered at Hex locations \$303 to \$311 (see listing Number 3).

After the move, the screen will display three lines of data, each 8 bytes long, and await entry of a new set of parameters. The three lines of data displayed on the screen are as follows:

- Line 1: The first 8 bytes of data starting at \$800, which is the fixed source data to be moved (in this case, the string A\$).
- Line 2: The first 8 bytes of data starting at the hex address entered as the destination of the move (high order byte only).
- Line 3: The first 8 bytes of data starting at \$0000 (the first four SWEET 16 registers).

The display of 8 bytes of data was chosen to simplify the illustration of what goes on.

Integer Basic has its own way of recording the string A\$. Because the name chosen for the string "A\$" is stored in 2 bytes, a total of five housekeeping bytes precede the data entered as A\$, leaving only three additional bytes available for display. Integer Basic also adds a housekeeping byte at the end of a string, known as the "string terminator".

Consequently, for convenience purposes of the display, and to see the string terminator as the 8th byte, the string data entered via the keyboard should be limited to two characters, and will appear as the 6th and 7th bytes. Additionally, parameters to be entered include the number of bytes to be moved. A useful range for this demonstration would be 1-8 inclusive, but of course 1-255 will work.

Finally, the starting address of the destination of the move must be entered. Again, for simplicity, only the high-order byte is entered, and the program allows a choice between Decimal 9 and high-order byte of program pointer 1, to avoid unnecessary problems (in this demonstration enter a decimal number between 9 and 144 for a 48K APPLE).

The 8 bytes of data displayed starting at \$00 will enable one to observe the condition of the SWEET 16 registers after a move has been accomplished, and thereby understand how the SWEET 16 program works.

From the article "SWEET 16: A 6502 Dream Machine", remember that SWEET 16 can establish 16 double byte registers starting at \$00. This means that SWEET 16 can use the first 32 addresses on zero page.

The "events" occurring in this demonstration program can be

studied in the first four SWEET 16 registers. Therefore, the 8 byte display starting at \$0000 is large enough for this purpose.

These four registers are established as R0, R1, R2, R3:

R0	\$0000	&	0001	- SWEET 16 accumulator
R1	\$0002	&	0003	- Source address
R2	\$0004	&	0005	- Destination address
R3	\$0006	&	0007	- Number of bytes to move
.
R14	\$001C	&	001D	- Prior result register
R15	\$001E	&	001F	- SWEET 16 Program counter

Additionally, an examination of registers R14 and R15 will extend and understanding of SWEET 16, as fully explained in the "WOZ" text. Notice that the high order byte of R14, (located at \$1D) contains \$06, and is the doubled register specification ($3 \times 2 = \$06$). R15, the SWEET 16 program counter contains the address of the next operation as it did for each step during execution of the program, which was \$0312 when execution ended and the 6502 code resumed.

To try a sample run, enter the Integer Basic program as shown in Listing #1. Of course, REM statements can be omitted, and line 10 is only helpful if the machine code is to be stored on disk. Listing #2 must also be entered starting at \$300.

NOTE: A 6502 disassembly does not look like listing #3, but the SOURCEROR assembler would create a correct disassembly.

Enter "RUN" and hit RETURN
Enter "12" and hit RETURN (A\$ - A\$ string data)
Enter "18" and hit RETURN (high-order byte of destination)

The display should appear as follows:

```
$0800-C1 40 00 10 08 B1 B2 1E (SOURCE)
$0A00-C1 40 00 10 08 B1 B2 1E (Dest.)
$0000-1E 00 08 08 08 0A 00 00 (SWEET 16)
```

NOTE: The 8 bytes stored at \$0A00 are identical to the 8 bytes starting at \$0800, indicating that an accurate move of 8 bytes length has been made. They are moved one byte at a time starting with token C1 and ending with token 1E. If moving less than 8 bytes, the data following the moved data would be whatever existed at those locations before the move.

The bytes have the following significance:

A Token\$

C1	40	00	10	08	B1	B2	1E
-----	-----	-----	-----	-----	-----	-----	--

VN	DSP	NVA	DATA	DATA	String Terminator
----	-----	-----	------	------	----------------------

The SWEET 16 registers are as shown:

\$0000	low 1E	high 00	low 08	high 08	low 08	high 0A	low 00	high 00
-----	-----	-----	-----	-----	-----	-----	-----	-----
	register R0 (acc)		register R1 (source)		register R2 (dest)		register R3 (#bytes)	

The low order byte of R0, the SWEET 16 accumulator, has \$1E init, the last byte moved (the 8th).

The low order byte of the source register R1 started as \$00 and was incremented eight times, once for each byte of moved data.

The high order byte of the destination register R2 contains \$0A, which was entered at 10 (the variable) and poked into the SWEET 16 code. The low-order byte of R2 was incremented exactly like R1.

Finally, register R3, the register that stores the number of bytes to be moved, has been poked to 8 (the variable B) and decremented eight times as each byte got moved, ending up \$0000.

By entering character strings and varying the number of bytes to be moved, the SWEET 16 registers can be observed and the contents predicted.

Working with this demonstration program, and study of the text material will enable you to write SWEET 16 programs that perform additional 16 bit manipulations. The unassigned opcodes mentioned in the "WOZ Dream Machine" article should present a most interesting opportunity to "play".

SWEET 16 as a language - or tool - opens a new direction to Apple][owners without spending a dime, and it's been there all the time.

"Apple-ites" who desire to learn machine language programming, can use SWEET 16 as a starting point. With this text material to use, and less opcodes to learn, a user can quickly be effective.

Listing #1

```
>List
10      PRINT "[D]BLOAD SWEET": REM CTRL D
20      CALL - 936: DIM A$ (10)
30      INPUT "ENTER STRING A$ ", A$
```

```
40 INPUT "ENTER # BYTES ", B
50 IF NOT B THEN 40 : REM AT LEAST 1
60 POKE 778, B : REM POKE LENGTH
70 INPUT "ENTER DESTINATION ", A
80 IF A > PEEK (203) - 1 THEN 70
90 IF A < PEEK (205) + 1 THEN 70
100 POKE 776, A : REM POKE DESTINATION
110 M = 8 : GOSUB 160 : REM DISPLAY
120 CALL 768 : REM GOTO $0300
130 M = A : GOSUB 160 : REM DISPLAY
140 M = 0 : GOSUB 160 : REM DISPLAY
150 PRINT : PRINT : GOTO 30
160 POKE 60, 0 : POKE 61, M
170 CALL -605 : RETURN : REM XAM8 IN MONITOR
```

Listing #2

+-----

Wozpak] [, November 1979, pages 109-115.

FLOATING POINT PACKAGE

The mantissa-exponent, or 'floating point' numerical representation is widely used by computers to express values with a wide dynamic range. With floating point representation, the number 7.5×10^{22} requires no more memory to store than the number 75 does. We have allowed for binary floating point arithmetic on the APPLE][computer by providing a useful subroutine package in ROM, which performs the common arithmetic functions. Maximum precision is retained by these routines and overflow conditions such as 'divide by zero' are trapped for the user. The 4-byte floating point number representation is compatible with future APPLE products such as floating point BASIC.

A small amount of memory in Page Zero is dedicated to the floating point workspace, including the two floating-point accumulators, FP1 and FP2. After placing operands in these accumulators, the user calls subroutines in the ROM which perform the desired arithmetic operations, leaving results in FP1. Should an overflow condition occur, a jump to location \$3F5 is executed, allowing a user routine to take appropriate action.

FLOATING POINT REPRESENTATION

Exponent Signed Mantissa

1. Mantissa

The floating point mantissa is stored in two's complement representation with the sign at the most significant bit (MSB) position of the high-order mantissa byte. The mantissa provides 24 bits of precision, including sign, and can represent 24-bit integers precisely. Extending precision is simply a matter of adding bytes at the low order end of the mantissa.

Except for magnitudes less than 2^{-128} (which lose precision) mantissa are normalized by the floating point routines to retain maximum precision. That is, the numbers are adjusted so that the upper two high-order mantissa bits are unequal.

- HI GH- ORDER MANTI SSA BYTE
- 01. XXXXX Positive mantissa.
 - 10. XXXXX Negative mantissa.
 - 00. XXXXX Unnormalized mantissa.
 - 11. XXXXX Exponent = - 128.

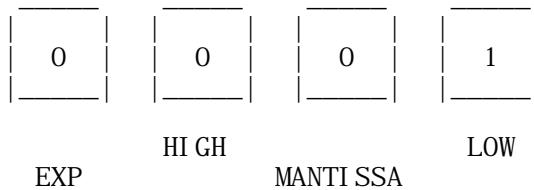

2. Exponent.

The exponent is a binary scaling factor (power of two) which is applied to the mantissa. Ranging from -128 to +127, the exponent is stored in standard two's complement representation except for the sign bit which is complemented. This representation allows direct comparison of exponents, since they are stored in increasing numerical sequence. The most negative exponent, corresponding to the smallest magnitude, -128, is stored as \$00 (\$ means hex decimal) and the most positive, +127, is stored as \$FF (all ones).

EXPONENT	STORED AS
+127	11111111 (\$FF)
+3	10000011 (\$83)
+2	10000010 (\$82)
+1	10000001 (\$81)
0	10000000 (\$80)
-1	01111111 (\$7F)
-2	01111110 (\$7E)
-3	01111101 (\$7D)
-128	00000000 (\$00)

The smallest magnitude which can be represented is 2^{-150} .

The largest positive magnitude which can be represented is $+2^{128-1}$.

FLOATING POINT REPRESENTATION EXAMPLES

DECIMAL NUMBER	HEX EXPONENT	HEX MANTISSA
+ 3	81	60 00 00
+ 4	82	40 00 00
+ 5	82	50 00 00
+ 7	82	70 00 00
+12	83	60 00 00
+15	83	78 00 00
+17	84	44 00 00
+20	84	50 00 00
+60	85	78 00 00

- 3	81	A0 00 00
- 4	81	80 00 00
- 5	82	B0 00 00
- 7	82	90 00 00
- 12	83	A0 00 00
- 15	83	88 00 00
- 17	84	BC 00 00
- 20	84	B0 00 00
- 60	85	88 00 00

FLOATING POINT SUBROUTINE DESCRIPTIONS

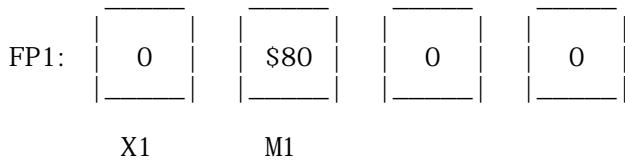

FCOMPL subroutine (address \$F4A4)

Purpose: FCOMPL is used to negate floating point numbers.

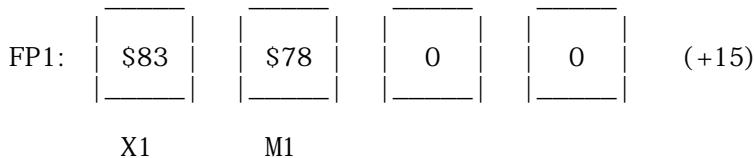

Entry: A normalized or unnormalized value is in FP1 (floating point accumulator 1).

Uses: NORM, RTLOG.

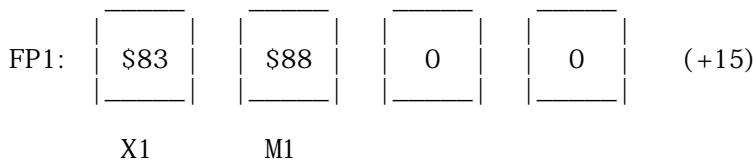

Exit: The value in FP1 is negated and then normalized to retain precision. The 3-byte FP1 extension, E, may also be altered but FP2 and SIGN are not disturbed. The 6502 A-REG is altered and the X-REG is cleared. The Y-REG is not disturbed.

Caution: Attempting to negate -2^{128} will result in an overflow since $+2^{128}$ is not representable, and a jump to location \$3F5 will be executed, with the following contents in FP1.

Example: Prior to calling FCOMPL, FP1 contains +15.

After calling FCOMPL as a subroutine, FP1 contains -15.

FADD subroutine (address \$F46E)

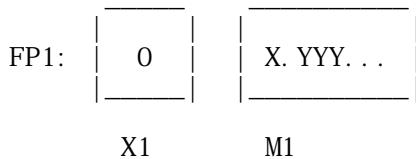

Purpose: To add two numbers in floating point form.

Entry: The two addends are in FP1 and FP2 respectively. For maximum precision, both should be normalized.

Uses: SWPALGN, ADD, NORM, RTLOG.

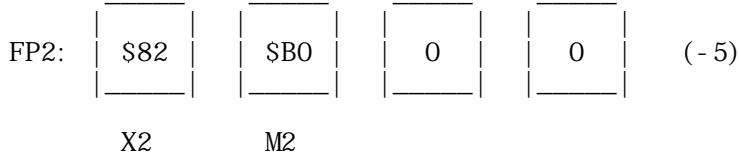

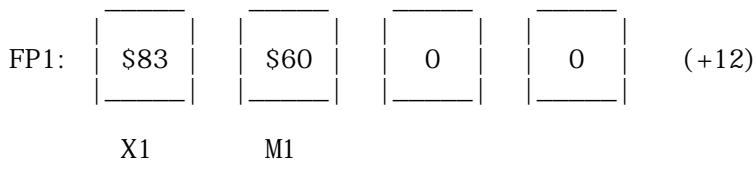

Exit: The normalized sum is left in FP1. FP2 contains the addend of greatest magnitude. E is altered but sign is not. The A-REG is altered and the X-REG is cleared. The sum mantissa is truncated to 24 bits.

Caution: Overflow may result if the sum is less than -2^{128} or greater than $+2^{128}-1$. If so, a jump to location \$3F5 is executed leaving 0 in X1, and twice the proper sum in the mantissa M1. The sign bit is left in the carry, 0 for positive, 1 for negative.

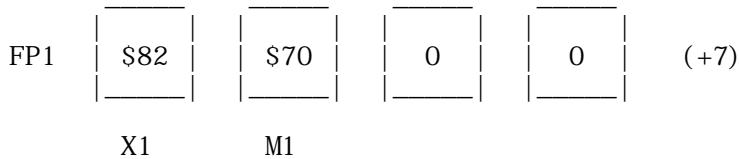

(For carry=0, true sum= $+X. YYY \times 2^{128}$)

Example: Prior to calling FADD, FP1 contains +12 and FP2 contains -5.

After calling FADD, FP1 contains +7 (FP2 contains +12).

FSUB subroutine (address \$F468)

Purpose: To subtract two floating point numbers.

Entry: The minuend is in FP1 and the subtrahend is in FP2. Both should be normalized to retain maximum precision prior to calling FSUB.

Uses: FCOMPL, ALGNSWP, FADD, ADD, NORM, RTLOG.

Exit: The normalized difference is in FP1 with the mantissa truncated to 24 bits. FP2 holds either the minuend or the negated subtrahend, whichever is of greater magnitude. E is altered but SIGN and SCR are not. the A-REG is altered and the X-REG is cleared. The Y-REG is not disturbed.

Cautions: An exit to location S3F5 is taken if the result is less than -2^{128} or greater than $+2^{128}-1$. or if the subtrahend is -2^{128} .

Example: Prior to calling FSUB, FP1 contains +7 (minuend) and FP2 contains -5 (subtrahend).

FP1:

\$82

\$70

0

0

 (+12)
X1 M1

FP2:

\$82

\$B0

0

0

 (- 5)
X2 M2

After calling FSUB, FP1 contains +12 and FP2 contains +7.

FP1:

\$83

\$60

0

0

 (+12)
X1 M1

FMUL subroutine (address \$F48C)

Purpose: To multiply floating point numbers.

Entry: The multiplicand and multiplier must reside in FP1 and FP2 respectively. Both should be normalized prior to calling FMUL to retain maximum precision.

Uses: MD1, MD2, RTLOG1, ADD, MDEND.

Exit: The signed normalized floating point product is left in FP1. M1 is

truncated to contain the 24 most significant mantissa bits (including sign). The absolute value of the multiplier mantissa (M2) is left in FP2. E, SIGN, and SCR are altered. The A- and X-REGs are altered and the Y-REG contains \$FF upon exit.

Cautions: An exit to location \$3F5 is taken if the product is less than -2^{128} or greater than $+2^{128}-1$.

Notes: FMUL will run faster if the absolute value of the multiplier mantissa contains fewer '1's than the absolute value of the multiplicand mantissa.

Example: Prior to calling FMUL, FP1 contains +12 and FP2 contains -5.

FP1:	<table border="1"><tr><td>\$83</td></tr><tr><td> </td></tr></table>	\$83		<table border="1"><tr><td>\$60</td></tr><tr><td> </td></tr></table>	\$60		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+12)

0													
	X1	M1											
FP2:	<table border="1"><tr><td>\$82</td></tr><tr><td> </td></tr></table>	\$82		<table border="1"><tr><td>\$50</td></tr><tr><td> </td></tr></table>	\$50		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+ 5)
\$82													
\$50													
0													
0													
	X2	M2											

FDIV subroutine (addr \$F4B2)

Purpose: To perform division of floating point numbers.

Entry: The normalized dividend is in FP2 and the normalized divisor is in FP1.

Exit: The signed normalized floating point quotient is left in FP1. The mantissa (M1) is truncated to 24 bits. The 3-bit M1 extension (E) contains the absolute value of the divisor mantissa. MD2, SIGN, and SCR are

altered. The A- and X-REGs are altered and the Y-REG is cleared.

Uses: MD1, MD2, MDEND.

Cautions: An exit to location \$3F5 is taken if the quotient is less than -2^{128} or greater than $+2^{128}-1$

Notes: MD2 contains the remainder mantissa (equivalent to the MOD function). The remainder exponent is the same as the quotient exponent, or 1 less if the dividend mantissa magnitude is less than the divisor mantissa magnitude.

Example: Prior to calling FDIV, FP1 contains -60 (dividend), and FP2 contains +12 (divisor).

FP1:

\$85	\$80	0	0

 (-60)
X1 M1

FP2:

\$83	\$60	0	0

 (+12)
X1 M1

After calling FMUL, FP1 contains -5 and M2 contains 0.

FP1:

\$82	\$B0	0	0

 (-5)
X1 M1

FLOAT Subroutine (address \$F451)

Purpose: To convert integers to floating point representation.

Entry: A signed (two's complement) 2-byte integer is stored in M1 (high-order byte) and M1+1 (low-order byte). M1+2 must be cleared by user prior to entry.

Uses: NORM1.

Exit: The normalized floating point equivalent is left in FP1. E, FP2, SIGN, and SCR are not disturbed. The A-REG contains a copy of the high-order mantissa byte upon exit but the X- and Y-REGs are not disturbed. The carry is cleared.

Notes: To float a 1-byte integer, place it in M1+1 and clear M1 as well as

M1+2 prior to calling FLOAT.

FLOAT takes approximately 3 msec. longer to convert zero to floating point form than other arguments. The user may check for zero prior to calling FLOAT and increase throughput.

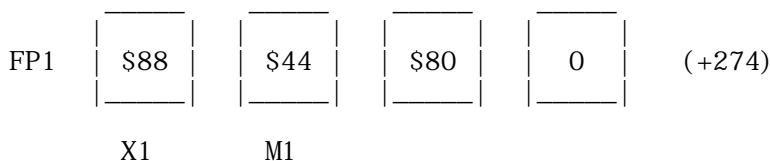

```
*  
* LOW- ORDER INT. BYTE IN A- REG  
* HI GH- ORDER BYTE IN Y- REG  
*  
85 FA XFLOAT STA M1+1  
84 F9 STY M1 INIT MANT1  
A0 00 LDY #$0  
84 FB STY M1+2  
05 D9 ORA M1 CHK BOTH  
                   BYTES FOR  
D0 03 BNE TOFLOAT ZERO  
85 F8 STA X1 IF SO CLR X1  
60 RTS AND RETURN  
4C 51 F4 TOFLOAT JMP FLOAT ELSE FLOAT  
                   INTEGER
```

Example: Float +274 (\$0112 hex)

CALLING SEQUENCE

```
A0 01 LDY #$01 HI GH- ORDER  
                   INTEGER BYTE  
A9 12 LDA #$12 LOW- ORDER  
                   INTEGER BYTE  
84 F9 STY M1  
85 FA STA M1+1  
A9 00 LDA #$00  
85 F8 STA M1+2  
20 51 F4 JSR FLOAT
```

Upon returning from FLOAT, FP1 contains the floating point representation of +274.

FIX subroutine (address \$F640)

Purpose: To extract the integer portion of a floating point number with truncation (ENTIER function).

Entry: A floating point value is in FP1. It need not be normalized.

Uses: RTAR.

Exit: The two-byte signed two's complement representation of the integer portion is left in M1 (high-order byte) and M1+1 (low-order byte). The floating point values +24.63 and -61.2 are converted to the integers +24 and -61 respectively. FP1 and E are altered but FP2, E, SIGN, and SCR are not. The A- and X-REGs are altered but the Y-REG is not.

Example: The floating point value +274 is in FP1 prior to calling FIX.

FP1:	<table border="1"><tr><td>\$88</td></tr><tr><td> </td></tr></table>	\$88		<table border="1"><tr><td>\$44</td></tr><tr><td> </td></tr></table>	\$44		<table border="1"><tr><td>\$80</td></tr><tr><td> </td></tr></table>	\$80		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+274)
\$88													
\$44													
\$80													
0													
	X1	M1											

After calling FIX, M1 (high-order byte) and M1+1 (low-order byte) contain the integer representation of +274 (\$0112).

FP1:	<table border="1"><tr><td>\$8E</td></tr><tr><td> </td></tr></table>	\$8E		<table border="1"><tr><td>\$01</td></tr><tr><td> </td></tr></table>	\$01		<table border="1"><tr><td>\$12</td></tr><tr><td> </td></tr></table>	\$12		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		
\$8E													
\$01													
\$12													
0													
	X1	M1											

Note: FP1 contains an unnormalized representation of +274 upon exit.

NORM Subroutine (address \$F463)

Purpose: To normalize the value in FP1, thus insuring maximum precision.

Entry: A normalized or unnormalized value is in FP1.

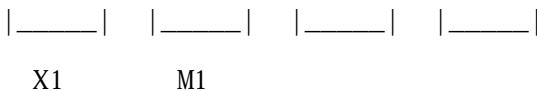

Exit: The value in FP1 is normalized. A zero mantissa will exit with X1=0 (2 exponent). If the exponent on exit is -128 (X1=0) then the mantissa (M1) is not necessarily normalized (with the two high-order mantissa bits unequal). E, FP2, SIGN, AND SCR are not disturbed. The A-REG is disturbed but the X- and Y-REGs are not. The carry is set.

Example: FP1 contains +12 in unnormalized form (as .0011 x 2).

FP1:	<table border="1"><tr><td>\$86</td></tr><tr><td> </td></tr></table>	\$86		<table border="1"><tr><td>\$0C</td></tr><tr><td> </td></tr></table>	\$0C		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+12)
\$86													
\$0C													
0													
0													
	x1	M1											

Upon exit from NORM, FP1 contains +12 in normalized form (as 1.1 x 2).

FP1:	<table border="1"><tr><td>\$83</td></tr><tr><td> </td></tr></table>	\$83		<table border="1"><tr><td>\$60</td></tr><tr><td> </td></tr></table>	\$60		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+12)
\$83													
\$60													
0													
0													

NORM1 subroutine (address SF455)

Purpose: To normalize a floating point value in FP1 when it is known the exponent is not -128 (X1=0) upon entry.

Entry: An unnormalized number is in FP1. The exponent byte should not be 0 for normal use.

Exit: The normalized value is in FP1. E, FP2, SIGN, and SCR are not disturbed. The A-REG is altered but the X- and Y-REGs are not.

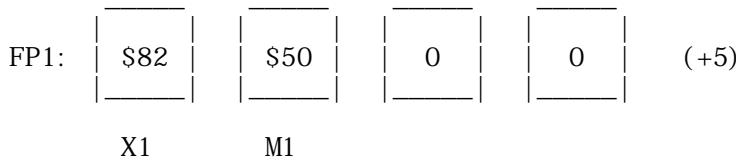

ADD Subroutine (address SF425)

Purpose: To add the two mantissas (M1 and M2) as 3-byte integers.

Entry: Two mantissas are in M1 (through M1+2) and M2 (through M2+2). They should be aligned, that is with identical exponents, for use in the FADD and FSUB subroutines.

Exit: the 24-bit integer sum is in M1 (high-order byte in M1, low-order byte in M1+2). FP2, X1, E, SIGN and SCR are not disturbed. The A-REG contains the high-order byte of the sum, the X-REG contains \$FF and the Y-REG is not altered. The carry is the '25th' sum bit.

Example: FP1 contains +5 and FP2 contains +7 prior to calling ADD.

Upon exit, M1 contains the overflow value for +12. Note that the sign bit is incorrect. This is taken care of with a call to the right shift routine.

ABSWAP Subroutine (address \$F437)

Purpose: To take the absolute value of FP1 and then swap FP1 with FP2. Note that two sequential calls to ABSWAP will take the absolute values of both FP1 and FP2 in preparation for a multiply or divide.

Entry: FP1 and FP2 contain floating point values.

Exit: The absolute value of the original FP1 contents are in FP2 and the original FP2 contents are in FP1. The least significant bit of SIGN is complemented if a negation takes place (if the original FP1 contents are negative) by means of an increment. SCR and E are used. The A-REG contains a copy of X2, the X-REG is cleared, and the Y-REG is not altered.

RTAR Subroutine (address \$F47D)

Purpose: To shift M1 right one bit position while incrementing X1 to compensate for scale. This is roughly the opposite of the NORM subroutine.

Entry: A normalized or unnormalized floating point value is in FP1.

Exit: The 6-byte field MANT1 and E is shifted right one bit arithmetically and X1 is incremented by 1 to retain proper scale. The sign bit of MANT1 (MSB of M1) is unchanged. FP2, SIGN, and SCR are not disturbed. The A-REG contains the least significant byte of E (E+2), the X-REG is cleared, and the Y-REG is not disturbed.

Caution: If X1 increments of 0 (overflow) then an exit to location \$3F5 is taken, the A-REG contains the high-order MANT1 byte, M1 and X1 is cleared. FP2, SIGN, SCR, and the X- and Y-REGs are not disturbed.

Uses: RTLOG

Example: Prior to calling RTAR, FP1 contains the normalized value -7.

FP1	<table border="1"><tr><td>\$83</td></tr></table>	\$83	<table border="1"><tr><td>\$AO</td></tr></table>	\$AO	<table border="1"><tr><td>0</td></tr></table>	0	<table border="1"><tr><td>0</td></tr></table>	0	(-7)
\$83									
\$AO									
0									
0									
X1		M1							

After calling RTAR, FP1 contains the unnormalized value -7 (note that precision is lost off the low-order end of M1).

FP1	<table border="1"><tr><td>\$84</td></tr></table>	\$84	<table border="1"><tr><td>\$D0</td></tr></table>	\$D0	<table border="1"><tr><td>0</td></tr></table>	0	<table border="1"><tr><td>0</td></tr></table>	0	(-7)
\$84									
\$D0									
0									
0									
X1		M1							

Note: M1 sign bit is unchanged.

RTLOG subroutine (address SF480)

Purpose: To shift the 6-byte field MANT1 and E one bit to the right (toward the least significant bit). The 6502 carry bit is shifted into the high-order M1 bit. This is useful in correcting binary sum overflows.

Entry: A normalized or unnormalized floating point value is in FP1. The carry must be cleared or set by the user since it is shifted into the sign bit of M1.

Exit: Same as RTAR except that the sign of M1 is not preserved (it is set to the value of the carry bit on entry)

Caution: Same as RTAR.

Example: Prior to calling RTLOG, FP1 contains the normalized value -12 and the carry is clear.

FP1:	<table border="1"><tr><td>\$83</td></tr><tr><td> </td></tr></table>	\$83		<table border="1"><tr><td>\$A0</td></tr><tr><td> </td></tr></table>	\$A0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(-12)
\$83													
\$A0													
0													
0													
	X1		M1										

After calling RTLOG, M1 is shifted one bit to the right and the sign bit is clear. X1 is incremented by 1.

FP1:	<table border="1"><tr><td>\$84</td></tr><tr><td> </td></tr></table>	\$84		<table border="1"><tr><td>\$50</td></tr><tr><td> </td></tr></table>	\$50		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		<table border="1"><tr><td>0</td></tr><tr><td> </td></tr></table>	0		(+20)
\$84													
\$50													
0													
0													
	X1		M1										

Note: The bit shifted off the end of MANT1 is rotated into the high-order bit of the 3-byte extension E. The 3-byte E field is also shifted one bit to the right.

RTLOG1 subroutine (address SF484)

Purpose: To shift MANT1 and E right one bit without adjusting X1. This is used by the multiply loop. The carry is shifted into the sign bit of MANT1.

Entry: M1 and E contain a 6-byte unsigned field. E is the 3-byte low-order extension of MANT1.

Exit: Same as RTLOG except that X1 is not altered and an overflow exit cannot occur.

MD2 subroutine (address \$F4E2)

Purpose: To clear the 3-byte MANT1 field for FMUL and FDIV, check for initial result exponent overflow (and underflow), and initialize the X-REG to \$17 for loop counting.

Entry: the X-REG is cleared by the user since it is placed in the 3 bytes of MANT1. The A-REG contains the result of an exponent addition (FMUL) or subtraction (FDIV). The carry and sign status bits should be set according to this addition or subtraction for overflow and underflow determination.

Exit: The 3 bytes of M1 are cleared (or all set to the contents of the X-REG on Entry) and the Y-REG is loaded with \$17. The sign bit of the A-REG is complemented and a copy of the A-REG is stored in X1. FP2, SIGN, SCR, and the X-REG are not disturbed.

Uses: NORM.

Caution: Exponent overflow results in an exit to location \$3F5. Exponent underflow results in an early return from the calling subroutine (FDIV or FMUL) with a floating point zero in FP1. Because MD2 pops a return address off the stack, it may only be called by another subroutine.

Dr. Dobb's Journal, August 1976, pages 17-19.

Floating Point Routines for the 6502

by Roy Rankin, Department of Mechanical Engineering,
Stanford University, Stanford, CA 94305
(415) 497-1822

and

Steve Wozniak, Apple Computer Company
770 Welch Road, Suite 154
Palo Alto, CA 94304
(415) 326-4248

Editor's Note: Although these routines are for the 6502, it would appear that one could generate equivalent routines for most of the "traditional" microprocessors, relatively easily, by following the flow of the algorithms given in the excellent comments included in the program listing. This is particularly true of the transcendental functions, which were directly modeled after well-known and proven algorithms, and for which, the comments are relatively machine independent.

These floating point routines allow 6502 users to perform most of the more popular and desired floating point and transcendental functions, namely:

Natural Log - LOG
Common Log - LOG10
Exponential - EXP
Floating Add - FADD
Floating Subtract - FSUB
Floating Multiply - FMUL
Floating Divide - FDIV
Convert Floating to Fixed - FIX
Convert Fixed to Floating - FLOAT

They presume a four-byte floating point operand consisting of a one-byte exponent ranging from -128 to +127 and a 24-bit two's complement mantissa between 1.0 and 2.0.

The floating point routines were done by Steve Wozniak, one of the principals in Apple Computer Company. The transcendental functions were patterned after those offered by Hewlett-Packard for their HP2100 mini computer (with some modifications), and were done by Roy Rankin, a Ph.D. student at Stanford University.

There are three error traps; two for overflow, and one for prohibited logarithm argument. ERROR (1D06) is the error

exit used in the event of a non-positive log argument. OVFLW (1E3B) is the error exit for overflow occurring during calculation of e to some power. OVFL (1FE4) is the error exit for overflow in all of the floating point routines. There is no trap for underflow; in such cases, the result is set to 0.0.

All routines are called and exited in a uniform manner: The arguments(s) are placed in the specified floating point storage locations (for specifics, see the documentation preceding each routine in the listing), then a JSR is used to enter the desired routine. Upon normal completion, the called routine is exited via a subroutine return instruction (RTS).

Note: The preceding documentation was written by the Editor, based on phone conversations with Roy and studying the listing. There is a high probability that it is correct. However, since it was not written nor reviewed by the authors of these routines, the preceding documentation may contain errors in concept or in detail.

-- JCW, Jr.

In the Exponent:

00 Represents -128

...

7F Represents -1

80 Represents 0

81 Represents +1

...

FF Represents +127

ERRATA FOR RANKIN' S 6502
FLOATING POINT ROUTINES

Sept. 22, 1976

Dear Jim,

Subsequent to the publication of "Floating Point Routines for the 6502" (Vol. 1, No. 7) an error which I made in the LOG routine came to light which causes improper results if the argument is less than 1. The following changes will correct the error.

1. After: CONT JSR SWAP (1D07)
Add: A2 00 LDX =0 LOAD X FOR HIGH BYTE OF EXPONENT
2. After: STA M1+1 (1D12)
Delete:
 LDA =0
 STA M1
Add: 10 01 BPL *+3 IS EXPONENT NEGATIVE
 CA YES, SET X TO SFF
 86 09 STX M1 SET UPPER BYTE OF EXPONENT
3. Changes 1 and 2 shift the code by 3 bytes so add 3 to the addresses of the constants LN10 through MHLF whenever they are referenced. For example the address of LN10 changes from 1DCD to 1DD0. Note also that the entry point for LOG10 becomes 1DBF. The routines stays within the page and hence the following routines (EXP etc.) are not affected.

Yours truly,

Roy Rankin
Dep. of Mech. Eng.
Stanford University

Floating Point Routines for the 6502*

by Roy Rankin
Department of Mechanical Engineering, Stanford University

and Steve Wozniak
Apple Computer Company

*First appeared in Dr. DOBB's Journal of Computer Calisthenics & Orthodontia, Box 310, Menlo Park, CA 94025

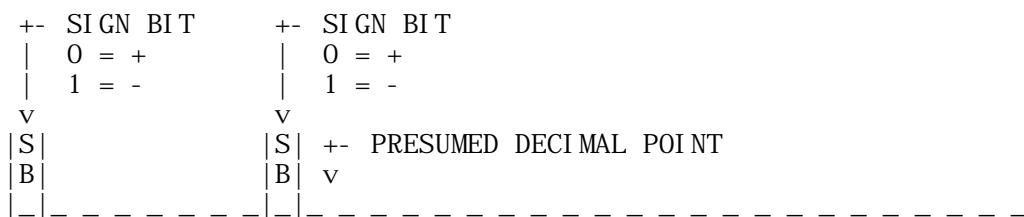

The following floating point routines represent a joint effort between Steve Wozniak who wrote the basic floating point routines of FADD, FSUB, FMUL, FDIV and their support routines and myself, Roy Rankin, who added FIX, FLOAT, LOG, LOG10, and EXP. The basic floating point routines are fairly machine dependent, but the transcendental programs should be very easy to transport from one machine to another. The routines consist of the following math functions

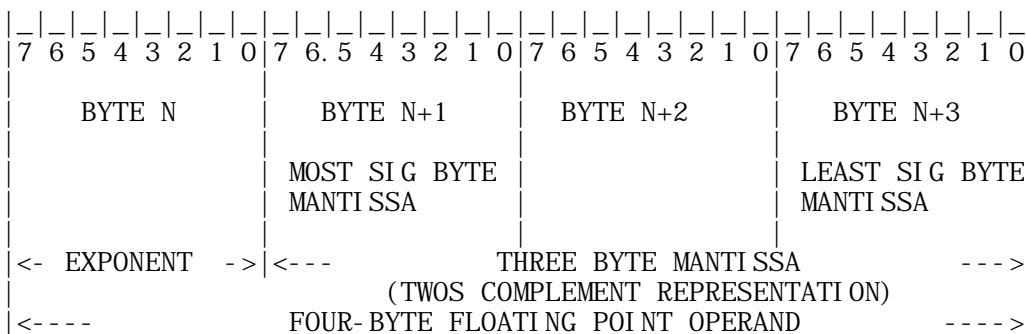

* LOG	Natural log
* LOG10	Base 10 log
* EXP	Exponential
* FADD	Floating add
* FSUB	Floating subtraction
* FMUL	Floating multiplication
* FDIV	Floating division
* FIX	Convert floating to fixed
* FLOAT	Convert fixed to floating

Two additional routines exchange the contents of `exp/mant1` with `exp/mant2` and complements `exp/mant1`. These routines are

SWAP Exchange the contents of exp/mant 1 with
FCOMPL Complement exp/mant 1

Floating point numbers are represented by 4 bytes as shown in the following

The exponent byte is a binary scaling factor for the Mantissa. The exponent is a standard two's complement representation except that the sign bit is complemented and runs from +128 to +127. For example:

```
$00 is -128
$01 is -127
*
*
$7F is -1
$80 is 0
$81 is -1
*
*
$FF is 127
```

The mantissa is standard two's complement representation with the sign bit in the most significant bit of the high order byte. The assumed decimal point is between bits 6 and 7 of the most significant byte. Thus the normalized mantissa ranges in absolute value from 1 to 2. Except when the exponent has a value of +128 the mantissa is normalized to retain maximum precision. The mantissa is normalized if the upper two bits of the high-order mantissa byte are unequal. Thus a normalized mantissa is of the following form:

```
01. xxxxxx positive mantissa (high byte)
10. xxxxxx negative mantissa (high byte)
Assumed binary point
```

Some sample floating point numbers in hex

83 50 00 00	10.
80 40 00 00	1.
7C 66 66 66	.1
00 00 00 00	0.
FC 99 99 9A	-.1
7F 80 00 00	-1.
83 B0 00 00	-10.

The routines are all entered using a JSR instruction. Base page locations \$004-\$007 are referred to as exp/mant2 while \$0008-000b are referred to as exp/

mant 1 and act as floating point registers. On entry to the subroutines these registers contain the numbers to be operated upon and contain the result on return. The function of the registers is given before each entry point in the source listing. There are three error traps which will cause a software interrupt. ERROT (1D06) is encountered if the argument in the log routine is less than or equal to zero. OVFLW (1E3B) will be executed if the argument of EXP is too large. Overflow detected by the basic floating point routines will cause OVFL (1FE4) to be executed. The routines do not give underflow errors, but set the number to zero if underflow occurs.

Readers of Dr. Dobbs' s journal should note that when these routines were published in that journal the math function LOG contained an error which prevented the correct result from being given if the argument was less than 1. This error has been corrected in the present listing and marked with "MOD 9/76."

```

tasm: Number of errors = 0

AIM 65 MICROCOMPUTER MONITOR PROGRAM LISTING
Rockwell International
Document No. 29650 N36L
Rev. 1, April 1979

I used the Telemark Cross Assembler v3.1 (TASM) to re-create the source code.
See <http://www.halcyon.com/squakvly/>

I tried to exactly duplicate the original source but some errors may exist.
The exceptions are when the original had a hexadecimal constant instead
of an ASCII constant or ASCII equate (especially CR) in some immediate
mode instructions; I changed them to ASCII constants or an equate.

For example, line 468 in the printed listing is:
0468 E185 A9 BC STA1 LDA #\$BC ; "<" CHR WITH MSB=1 FOR DISP

My version is:

0468 E185 A9 BC STA1 LDA #' <' +\$80 ; "<" CHR WITH MSB=1 FOR DISP

The TASM assembler is not the same one that Rockwell used to write the
code, so some assembler directives and opcode formats are different.
However, the ASM file uses the same line numbering as the printed listing.
That is, line 1000 in the printed listing corresponds to line 1000 in the
ASM file and line 1000 in the LST file.

I could not fully read eight lines in the program listing because I was
looking at a scanned copy, not the original. The rightmost characters
were lost in the binding. These are the lines:

```
0149 HI ST =NAME      ; FOUR LAST ADDR + NEXT (SINGL STEP)
1796   JSR SWSTAK    ; SWAP X, Y WITH RTRN ADDR FROM S
1804   JSR SWSTAK    ; SWAP X, Y WITH RTRN ADDR FROM
2159 RDBIT LDA TSPEED ; ARE WE IN C7 OR 5B, 5A FREQUENC
2262 OUTDP1 JMP (DLINK) ; HERE HE COULD ECHO SOMEWHERE ELSE
3205   BNE I NO2     ; CONTIN, DISP WONT ALLOW > 60 CHR
3719   LDA TYPE      ; CHCK FOR BRNCH WITH RELATIVE ADDR
3727 TRY34 LDA #04     ; CHECK FOR ABSOLUTE OR ZP, X OR ZP,
```

NOTE: I have since been told that the cut-off lines above exist in the
original manual.

H ATN Implementation

INTRODUCTION

Before a computer can perform any useful function, it must be "told" what to do. Unfortunately, at this time, computers are not capable of understanding English or any other "human" language. This is primarily because our languages are rich with ambiguities and implied meanings. The computer must be told precise instructions and the exact sequence of operations to be performed in order to accomplish any specific task. Therefore, in order to facilitate human communication with a computer, programming languages have been developed.

Rockwell AIM 65 8K BASIC by Microsoft is a programming language both easily understood and simple to use. It serves as an excellent "tool" for applications in areas such as business, science, and education. After only a few hours of using BASIC, you will find that you can already write programs with an ease that few other computer languages can duplicate.

Originally developed at Dartmouth University, the BASIC language has found wide acceptance in the computer field. Although it is one of the simplest computer languages to use, it is very powerful. BASIC uses a small set of common English words as its "commands." Designed specifically as an "interactive" language, you can give a command such as "PRINT 2 + 2," and BASIC will immediately reply with "4." It is not necessary to submit a card deck with your program on it and then wait hours for the results. Instead, the full power of the computer is "at your fingertips."

We hope that you enjoy BASIC, and are successful in using it to solve all of your programming

problems.

100 INSTALLING BASIC IN THE AIM 65

ROM INSTALLATION PROCEDURE

Before handling the BASIC ROM circuits, be sure to observe the precautions outlined in Section 1.4 of the AIM 65 User's Guide.

To install the ROMs, turn off power to the AIM 65. Inspect the pins on the two BASIC ROMs to ensure that they are straight and free of foreign material. While supporting the AIM 65 Master Module beneath the ROM socket, insert ROM number R3225 into Socket Z25, being careful to observe the device orientation. Now insert ROM number R3226 into Socket Z26. Be certain that both ROM's are completely inserted into their sockets, then turn on power to the AIM 65.

ENTERING BASIC

To enter and initialize BASIC, type 5 after the monitor prompt is displayed. AIM 65 will respond with:

<5>

MEMORY SIZE? ^

Type the highest address in memory that is to be allocated to the BASIC program, in decimal. End the entry by typing RETURN. BASIC will allocate memory from 530 (212 in hex) through the entered address. If BASIC is to use all available memory, type RETURN without entering an address. The highest address is 1024 (400 hex) in the 1K RAM version of AIM 65, and 4096 (1000 hex) in the 4K RAM version.

BASIC will then ask:

WIDTH? ^

Type in the output line width of the printer (or any other output device that is being used) and end the input with RETURN.

The entered number may vary from 1 to 255, depending on the output device. If RETURN is typed without entering a number, the output line width is set to a default value of 20, which is the column width of the AIM 65 printer.

BASIC will respond with:

XXXX BYTES FREE

where XXXX is the number of bytes available for BASIC program, variables, matrix storage, and string space. If all available memory was allocated, BASIC will reply with:

494 BYTES FREE (for 1K RAM; i.e., 1024-530)

or

3566 BYTES FREE (for 4K RAM; i.e., 4096-530)

BASIC will display:

^ AIM 65 BASIC Vn.n

where n.n is the version number.

BASIC is now in the command entry mode as indicated by the BASIC prompt (^) in the display column 1. Subject 201 gets you started into the BASIC commands.

Read the following paragraphs first, however, so understand how to exit and reenter the BASIC and how the BASIC cursor prompt operates.

CAUTION

Entering BASIC with the 5 key causes the allocated

memory to be initialized with AA (hex) in all bytes, starting with address 532. This, of course, destroys any previous BASIC programs, data in the AIM 65 Editor Text Buffer, or machine level routines that may have been stored in this portion of memory. Be sure to save any desired data or programs that may exist in this area before entering BASIC with the 5 key.

Note that text in the Text Buffer or machine level routine may co-exist in memory with BASIC by locating such text or routines in upper memory and entering the highest BASIC address with a value lower than the starting address of such text or routines.

EXITING BASIC

To escape from BASIC and return to the AIM 65 Monitor, type ESC any time the BASIC command cursor is displayed. You can also escape BASIC while a program is running, by pressing the F1 key (see Subject 301).

Pressing RESET will also cause the AIM 65 Monitor to be entered as well as performing a hardware reset of AIM 65.

REENTERING BASIC

BASIC may be reentered by typing 6 whenever the AIM 65 Monitor prompt is displayed. In this case, however, any existing BASIC program is retained in memory. AIM 65 will respond to a Key 6 entry with:

<6>
^6>

BASIC CURSOR

The BASIC cursor (^), displayed in column 1 whenever BASIC is in the command entry mode, indicates that a BASIC command can be entered. The last displayed data resulting from the previous command is retained except for column 1 to provide information continuity with the previous command or displayed output data. This is especially helpful when the printer control is turned off to preserve printer paper.

When the first character of the next command is typed, the display will blank except for the newly typed character. The cursor then advances across the display in accordance with typed characters to indicate the character input position.

The displayed cursor does not appear on the printer output, thus any data printed in column 1 will be retained.

CAUTION

The minus sign associated with any negative values that are displayed starting in column 1 will be replaced with the cursor in the BASIC command entry mode. In the case of direct commands, the minus sign will only flash before the cursor is displayed if the printer control is on or may not appear at all if the printer control is off. In order to retain the minus sign, a leading blank should be displayed before the value is displayed (see Subject 204).

PRINTER CONTROL

While in the BASIC command entry mode, the printer may be turned on or off by typing PRINT while CNTL is pressed (CNTL PRINT). The on/off state of the printer is displayed after typing PRINT.

If the printer is turned off, statements in the BASIC command entry mode and data output from

PRI NT commands will be directed to the display only. If the printer is turned on, all commands and data from PRINT commands will be directed to both the printer and display. With the printer off, data can still be directed to the printer by using the PRINT) command (see Subject 305).

Similarly, INPUT statements will output data to the printer in response to the printer control state. An INPUT! statement will output data to the printer even if the printer control is off (see Subject 305).

200 GETTING STARTED WITH BASIC

201 BASIC COMMAND SET

This section is not intended to be a detailed course in BASIC programming. It will, however, serve as an excellent introduction for those of you unfamiliar with the language.

We recommend that you try each example in this section as it is presented. This will enhance your "feel" for BASIC and how it is used. Table 201-1 lists all the AIM 65 BASIC commands.

NOTE

Any time the cursor (^) is displayed in column 1 a BASIC command may be typed in. End all commands to BASIC by typing RETURN. The RETURN tells BASIC that you have finished typing the command. If you make an error, type a DEL (RUBOUT on a TTY) to eliminate the last character. Repeated use of DEL will eliminate previous characters. An @ symbol will eliminate that entire line being typed.

Table 201.1. AIM 65 BASIC Commands

Commands	Input /Output
CLEAR	DATA
CONT	GET
FRE	INPUT
LIS T	POS
LOAD	PRI NT
NEW	READ
PEEK	SPC
POKE	TAB
RUN	
SAVE	
String Functions	
Program Statements	ASC
	CHRS

RESTORE	EXP
RETURN	INT
STOP	LOG
USR	RND
WAIT	SIN
	SGN
	SQR
	TAN
Arithmetic Functions	

* Although the ATN function is not included in AIM 65 BASIC, the ATN command is recognized (see Appendix H).

202 DIRECT AND INDIRECT COMMANDS

DIRECT COMMANDS

Try typing in the following:

PRINT 10-4 (end with RETURN)

BASIC will immediately print:

6

The print statement you typed in was executed as soon as you hit the RETURN key. This is called a direct command. BASIC evaluated the formula after the "PRINT" and then typed out its value, in this case "6".

Now try typing in this:

PRINT 1/2, 3*10 ("*" means multiply, "/" means divide)

BASIC will print:

.5 30

As you can see, BASIC can do division and multiplication as well as subtraction. Note how a "," (comma) was used in the print command to print two values instead of just one. The command divides a line into 10-character-wide columns. The comma causes BASIC to skip to the next 10-column field on the terminal, where the value 30 is printed.

INDIRECT COMMANDS

There is another type of command called an Indirect Command. Every Indirect command begins with a Line Number. A Line Number is any integer from 0 to 63999.

Try typing in these lines:

10 PRINT 2+3
20 PRINT 2-3

A sequence of Indirect Commands is called a "Program." Instead of executing indirect statements immediately, BASIC saves Indirect Commands in memory. When you type in RUN, BASIC will execute the lowest numbered indirect statement that has been typed in first, then the next higher, etc., for as many as were typed in.

In the example above, we typed in line 10 first and line 20 second. However, it makes no difference in what order you type in indirect statements. BASIC always puts them into correct numerical order according to the Line Number.

Suppose we type in

RUN

BASIC will print:

5
-1

203 OPERATING ON PROGRAMS AND LINES

In Subject 202, we typed a two-line program into memory. Now let's see how BASIC can be used to operate on either or both lines.

LISTING A PROGRAM

If we want a listing of the complete program currently in memory, we type in

LIST

BASIC will reply with:

```
10 PRINT 2+3
20 PRINT 2-3
```

DELETING A LINE

Sometimes it is desirable to delete a line of a program altogether. This is accomplished by typing the Line Number of the line so be deleted, followed by a carriage return.

Type in the following:

```
10
LIST
```

BASIC will reply with:

```
20 PRINT 2-3
```

We have now deleted line 10 from the program.

REPLACING A LINE

You can replace line 10, rather than just deleting it, by typing the new line 10 and hitting RETURN.

Type in the following:

```
10 PRINT 3-3
LIST
```

BASIC will reply with:

```
10 PRINT 3-3
20 PRINT 2-3
```

It is not recommended that lines be numbered consecutively. It may become necessary to insert a new line between two existing lines. An increment of 10 between line numbers is generally sufficient.

DELETING A PROGRAM

If you want to delete the complete program currently stored in memory, type in "NEW." If you are finished running one program and are about to read in a new one, be sure to type in "NEW" first.

Type in the following:

```
NEW
```

Now type in:

```
LIST
```

```
204 PRINTING DATA
```

If is often desirable to include explanatory text along with answers that are printed out.

Type in the following:

```
PRINT "ONE HALF EQUALS", 1/2
```

BASIC will reply with:

```
ONE THIR D EQUALS
.5
```

As explained in Subject 202, including a "," in a PRINT statement causes it to space over to the next 10-column field before the value following the "," is printed.

If we use a ";" instead of a comma, the next value will be printed immediately following the previous value.

NOTE

Numbers are always printed with at least one trailing space. Any text to be printed must always be enclosed in double quotes.

Try the following examples:

1. PRINT "ONE HALF EQUALS"; 1/2
ONE HALF EQUALS .5
2. PRINT 1, 2, 3
1 2
3
...
3. PRINT 1; 2; 3
1 2 3
4. PRINT -1; 2; -3
-1 2 -3

205 NUMBER FORMAT

We will digress for a moment to explain the format of numbers in BASIC. Numbers are stored internally to over nine digits of accuracy. When a number is printed, only nine digits are shown. Every number may also have an exponent (a power of ten scaling factor).

The largest number that may be presented in AIM 65 BASIC is 1.70141183*10^38, while the smallest positive number is 2.93873588*10^-39.

When a number is printed, the following rules define the format:

1. If the number is negative, a minus sign (-) is printed. If the number is positive, a space is printed.
2. If the absolute value of the number is an integer in the range 0 to 999999999, it is printed as an integer.
3. If the absolute value of the number is greater than or equal to 0.01 and less than or equal to 999999999, it is printed in fixed point notation, with no exponent.
4. If the number does not fall under categories 2 or 3, scientific notation is used.

Scientific notation is formatted as follows: SX.XXXXXXXXXESTT. (Each X is some integer, 0 to 9.)

The leading "S" is the sign of the number: a space for a positive number and a "-" for a negative one. One non-zero digit is printed before the decimal point. This is followed by the decimal point and then the other eight digits of the mantissa. An "E" is then printed (for exponent), followed by the sign (S) of the exponent; then the two digits (TT) of the exponent itself. Leading zeroes are never printed; i.e., the digit before the decimal is never zero. Trailing zeroes are never printed. If there is only one digit to print after all trailing zeroes are suppressed, no decimal point is printed. The exponent sign will be "+" for positive and "-" for negative. Two digits of the exponent are always printed; that is, zeroes are not suppressed in the exponent field. The value of any number expressed thus is the number so the left of the "E" times 10 raised to the power of the number to the right of the "E".

Regardless of what format is used, a space is always printed following a number. BASIC checks to see if the entire number will fit on the current line. If it cannot, a carriage return/line feed is executed before printing the number.

Following are examples of various numbers and the output format in which BASIC will output them:

NUMBER	OUTPUT FORMAT
-----	-----

+1	1
-1	-1
6523	6523
-23.460	-23.46
1E20	1E+20
-12.3456E-7	-1.23456E-06
1.234567E-10	1.23457E-10
1000000000	1E+09
999999999	999999999
.1	.1
.01	.01
.000123	1.23 E-04

A number input from the keyboard or a numeric constant used in a BASIC program may have as many digits as desired, up to the maximum length of a line (72 characters) or maximum numeric value. However, only the first 10 digits are significant, and tenth digit is rounded up.

```
PRI NT 1. 23456789876543210  
1. 2345679
```

206 VARIABLES

ASSIGNING VARIABLES WITH AN INPUT STATEMENT

Following is an example of a program that reads a value from the keyboard and uses that value to calculate and print a result:

```
10 INPUT R  
20 PRI NT 3. 14159*R*R  
RUN  
?10  
314. 159
```

Here's what's happening: When BASIC encounters the input statement, it outputs a question mark (?) on the display and then waits for you to type in a number. When you do (in the above example, 10 was typed), execution continues with the next statement in the program after the variable (R) has been set (in this case to 10). In the above example, line 20 would now be executed. When the formula after the PRINT statement is evaluated, the value 10 is substituted for the variable R each time R appears in the formula. Therefore, the formula becomes $3.14159 * 10 * 10$, or 314.159.

If we wanted to calculate the area of various circles, we could rerun the program for each successive circle. But, there's an easier way to do it simply by adding another line to the program, as follows:

```
30 GOTO 10  
RUN  
?10  
314. 159  
?3  
28. 27431  
?4. 7  
69. 3977231  
?
```

By putting a "GOTO" statement on the end of our program, we have caused it to go back to line 10 after it prints each answer for the successive circles. This could have gone on indefinitely, but we decided to stop after calculating the area for three circles. This was accomplished by typing a carriage return to the input statement (thus a blank line).

VARIABLE NAMES

The letter "R" in the program above is a "variable." A variable name can be any alphabetic character and may be followed by any alphanumeric character (letters A to Z, numbers 0 to 9).

Any alphanumeric characters after the first two are ignored.

Here are some examples of legal and illegal variable names:

Legal	Illegal
A	% (first character must be alphabetic)

Z1	ZI ABCD (variable name too long)
TP	TO (variable names cannot be reserved words)
PSTGS COUNT	RGOTO (variable names cannot contain reserved words)

ASSIGNING VARIABLES WITH A LET OR ASSIGNMENT STATEMENT

Besides having values assigned to variables with an input statement, you can also set the value of a variable with a LET or assignment statement.

Try the following examples:

```
A=5
PRINT A, A*2
5      10
LET Z=7
PRINT Z, Z-A
7      2
```

As you will notice from the examples, the "LET" is optional in an assignment statement.

BASIC "remembers" the values that have been assigned to variables using this type of statement. This "remembering" process uses space in the memory to store the data.

The values of variables are discarded (and the space in memory used to store them is released) when one of four conditions occur:

- * A new line is typed into the program or an old line is deleted
- * A CLEAR command is typed in
- * A RUN command is typed in
- * NEW is typed in

Another important fact is that if a variable is encountered in a formula before it is assigned a value, it is automatically assigned the value zero. Zero is then substituted as the value of the variable in the particular formula. Try the example below:

```
PRI NT Q; Q+2; Q*2
0 2 0
```

RESERVED WORDS

The words used as BASIC statements are "reserved" for this specific purpose. You cannot use these words as variable names or inside of any variable name. For instance, "FEND" would be illegal because "END" is a reserved word.

Table 206-1 is a list of the reserved words in BASIC.

Table 206-1. AIM 65 BASIC Reserved Words

ABS	FN	LIST	PRI NT	SPC
AND	FOR	LOAD	POS	SQR
ASC	FRE	LOG	READ	STEP
ATN	GET	MIDS	REM	STOP
CHR\$	GOSUB	NEW	RESTORE	STR\$
CLEAR	GOTO	NEXT	RETURN	TAB
CONT	IF	NOT	RIGHT\$	TAN
COS	INPUT	NULL	RND	THEN
DATA	INT	ON	RUN	TO
DEF	LEFT\$	OR	SAVE	USR
DIM	LEN	PEEK	SGN	VAL
END	LET	POKE	SIN	WAIT
EXP				

REMARKS

The REM (short for "remark") statement is used to insert comments or notes into a program. When BASIC encounters a REM statement, the rest of the line is ignored.

This serves mainly as an aid for the programmer and serves no useful function as far as the operation of the program in solving a particular problem.

207 RELATIONAL TESTS

Suppose we wanted to write a program to check whether a number is zero. With the statements we've gone over so far, this could not be done. What is needed is a statement which can be used to conditionally branch to another statement. The "IF-THEN" statement does just that.

Type in the following program: (remember, type NEW first)

```
10 INPUT B
20 IF B=0 THEN 55
30 PRINT "NON-ZERO"
40 GOTO 10
50 PRINT "ZERO"
60 GOTO 10
```

When this program is typed and run, it will ask for a value for B. Type in any value you wish. The AIM 65 will then come to the "IF" statement. Between the "IF" and the "THEN" portion of the statement there are two expressions separated by a "relation."

A relation is one of the following six symbols:

RELATION	MEANING
=	EQUAL TO
>	GREATER THAN
<	LESS THAN
<>	NOT EQUAL TO
<= or <=	LESS THAN OR EQUAL TO
=> or =>	GREATER THAN OR EQUAL TO

The IF statement is either true or false, depending upon whether the two expressions satisfy the relation. For example, in the program we just did, if 0 was typed in for B the IF statement would be true because $0=0$. In this case, since the number after the THEN is 50, execution of the program would continue at line 50. Therefore, "ZERO" would be printed and then the program would jump back to line 10 (because of the GOTO statement in line 60).

Suppose a 1 was typed in for B. Since $1=0$ is false, the IF statement would be false and the program would continue execution with the next line. Therefore, "NON-ZERO" would be printed and the GOTO in line 40 would send the program back to line 10.

A PROGRAM USING RELATIONS

Now try the following program for comparing two numbers:

```
10 INPUT A,B
20 IF A<=B THEN 50
30 PRINT "A IS BIGGER"
40 GOTO 10
50 IF A<B THEN 80
60 PRINT "THEY ARE THE SAME"
70 GOTO 10
80 PRINT "B IS BIGGER"
90 GOTO 10
```

When this program is run, line 10 will input two numbers from the keyboard. At line 20, if A is greater than B, $A \leq B$ will be false. This will cause the next statement to be executed, printing "A IS BIGGER" and then line 40 sends the computer back to line 10 to begin again.

At line 20, if A has the same value as B, $A \leq B$ is true so we go to line 50. At line 50, since A has the same value as B, $A < B$ is false; therefore, we go to the following statement and print "THEY ARE THE SAME." Then line 70 sends us back to the beginning again.

At line 20, if A is smaller than B, A<B is true so we goto line 50. At line 50, A<B will be true so we then go to line 80. "B IS BIGGER" is then printed and again we go back to the beginning.

Try running the last two programs several times. It may be easier to understand if you try writing your own program at this time using the IF-THEN statement. Actually trying programs of your own is the quickest and easiest way to understand how BASIC works. Remember, to stop these programs just give a RETURN to the input statement.

208 LOOPING

One advantage of computers is their ability to perform repetitive tasks. Let's take a closer look and see how this works.

A SQUARE ROOT PROGRAM

Suppose we want a table of square roots from 1 to 9. The BASIC function for square root is "SQR"; the form being SQR(X), X being the number whose square root is to be calculated. We could write the program as follows:

```
10 PRINT 1, SQR(1)
20 PRINT 2, SQR(2)
30 PRINT 3, SQR(3)
40 PRINT 4, SQR(4)
50 PRINT 5, SQR(5)
60 PRINT 6, SQR(6)
70 PRINT 7, SQR(7)
80 PRINT 8, SQR(8)
90 PRINT 9, SQR(9)
```

AN IMPROVED SQUARE ROOT PROGRAM

This program will do the job, but is terribly inefficient. We can improve the program considerably by using the IF statement just introduced as follows:

```
10 N=1
20 PRINT N; SQR(N)
3D N=N+1
40 IF N<=9 THEN 20
```

When this program is run, its output will look exactly like that of the 9 statement program above it. Let's look at how it works:

At line 10 we have a LET statement which sets the value of the variable N equal to 1. At line 20 we print N and the square root of N using its current value. It thus becomes 20 PRINT 1; SQR(1), and this calculation is printed out.

At line 30 we use what will appear at first to be a rather unusual LET statement. Mathematically, the statement N=N+1 is nonsense. However, the important thing to remember is that in a LET statement, the symbol "=" does not signify equality. In this case, "=" means "to be replaced with." All the statement does is to take the current value of N and add 1 to it. Thus, after the first time through line 30, N becomes 2.

At line 40, since N now equals 2, N<=9 is true so the THEN portion branches us back to line 20, with N now at a value of 2.

The overall result is that lines 20 through 40 are repeated, each time adding 1 to the value of N. When N finally equals 9 at line 20, the next line will increment it to 11. This results in a false statement at line 40, and since there are no further statements to the program it stops.

BASIC STATEMENTS FOR LOOPING

This technique is referred to as "looping" or "iteration." Since it is used quite extensively in programming, there are special BASIC statements for using it. We can show these with the following program:

```
10 FOR N=1 TO 9
20 PRINT N; SQR(N)
30 NEXT N
```

The output of the program listed above will be exactly the same as the previous two programs.

At line 10, N is set to equal 1. Line 20 causes the value of N and the square root of N so be printed. At line 30 we see a new type of statement. The "NEXT N" statement causes one to be added to N, and then if N<=9 we go back to the statement following the "FOR" statement. The overall operation then is the same as with the previous program.

Notice that the variable following the "FOR" is exactly the same as the variable after the "NEXT." There is nothing special about the N in this case. Any variable could be used, as long as it is the same in both the "FOR" and the "NEXT" statements. For instance, "Z1" could be substituted everywhere there is an "N" in the above program and it would function exactly the same.

ANOTHER SQUARE ROOT PROGRAM

Suppose we want to print a table of square roots of each even number from 10 to 20. The following program performs this task:

```
10 N=10
20 PRINT N; SQR(N)
30 N=N+2
40 IF N<=20 THEN 20
```

Note the similarity between this program and our "improved" square root program. This program can also be written using the "FOR" loop just introduced.

```
10 FOR N=10 TO 20 STEP 2
20 PRINT N; SQR(N)
30 NEXT N
```

Notice that the only major difference between this program and the previous one using "FOR" loops is the addition of the "STEP 2" clause.

This tells BASIC to add 2 to N each time, instead of 1 as in the previous program. If no "STEP" is given in a "FOR" statement, BASIC assumes that 1 is to be added each time. The "STEP" can be followed by any expression.

A COUNT-BACKWARD PROGRAM

Suppose we wanted to count backward from 10 to 1. A program for doing this would be as follows:

```
10 I=10
20 PRINT I
30 I=I-1
40 IF I>=1 THEN 20
```

Notice that we are now checking to see that I is greater than or equal to the final value. The reason is that we are now counting by a negative number. In the previous examples it was the opposite, so we were checking for a variable less than or equal to the final value.

SOME OTHER LOOPING OPERATIONS

The "STEP" statement previously shown can also be used with negative numbers to accomplish this same result. This can be done using the same format as in the other program:

```
10 FOR I=10 TO 1 STEP -1
20 PRINT I
30 NEXT I
```

"FOR" loops can also be "nested." For example:

```
10 FOR I=1 TO 5
20 FOR J=1 TO 3
30 PRINT I, J
40 NEXT J
50 NEXT I
```

Notice that "NEXT J" precedes "NEXT I." This is because the J-loop is inside the I-loop. The following program is incorrect; run it and see what happens:

```
10 FOR I=1 TO 5
20 FOR J=1 TO 3
30 PRINT I,J
40 NEXT I
50 NEXT J
```

It does not work because when the "NEXT I" is encountered, all knowledge of the J-loop is lost. This happens because the J-loop is "inside" the I-loop.

209 MATRIX OPERATIONS

It is often convenient to be able to select any element in a table of numbers. BASIC allows this to be done through the use of matrices.

A matrix is a table of numbers. The name of this table (the matrix name) is any legal variable name, "A" for example. The matrix name "A" is distinct and separate from the simple variable "A," and you could use both in the same program.

To select an element of the table, we subscript "A": that is, to select the I'th element, we enclose I in parentheses "(I)" and then follow "A" by this subscript. Therefore, "A(I)" is the I'th element in the matrix "A."

"A(1)" is only one element of matrix A, and BASIC must be told how much space to allocate for the entire matrix. This is done with a "DIM" statement, using the format "DIM A(15)." In this case, we have reserved space for the matrix index "I" to go from 0 to 15. Matrix subscripts always start as 0; therefore, in the above example, we have allowed for 16 numbers in matrix A.

If "A(1)" is used in a program before it has been dimensioned, BASIC reserves space for 11 elements (0 through 10).

A SORT PROGRAM

As an example of how matrices are used, try the following program to sort a list of 8 numbers, in which you pick the numbers to be sorted:

```
10 DIM A(8)
20 FOR I=1 TO 8
30 INPUT A(I)
40 NEXT I
50 F=0
60 FOR I=1 TO 7
70 IF A(I)<=A(I+1) THEN 140
80 T=A(I)
90 A(I)=A(I+1)
100 A(I+1)=T
110 F=1
120 NEXT I
130 IF F=1 THEN 70
140 FOR I=1 TO 8
150 IF F=1 THEN 70
160 FOR I=1 TO 8
170 PRINT A(I)
180 NEXT I
```

When line 10 is executed, BASIC sets aside space for 9 numeric values, A(0) through A(8). Lines 20 through 50 get the unsorted list from the user. The sorting itself is done by going through the list of numbers and switching any two that are not in order. "F" is used to indicate if any switches were made; if any were made, line 150 tells BASIC to go back and check some more.

If we did not switch any numbers, or after they are all in order, lines 160 through 180 will print out the sorted list. Note that a subscript can be any expression.

210 SUBROUTINES

If you have a program that performs the same action in several different places, you could duplicate the same statements for the action in each place within the program.

The "GOSUB" and "RETURN" statements can be used to avoid this duplication. When a "GOSUB" is encountered, BASIC branches to the line whose number follows the "GOSUB." However, BASIC remembers where it was in the program before it branches. When the "RETURN" statement is encountered, BASIC goes back to the first statement following the last "GOSUB" that was executed. Observe the following program:

```
10 PRINT "WHAT IS THE NUMBER";
20 GOSUB 100
30 T=N
40 PRINT "SECOND NUMBER";
50 GOSUB 100
60 T=N+T
70 PRINT "THE SUM IS"; T
80 STOP
```

```
100 INPUT N
110 IF N=INT(N) THEN 140
120 PRINT "MUST BE INTEGER."
130 GOTO 100
140 RETURN
```

This program asks for two numbers (which must be integers), and then prints their sum. The subroutine in this program is lines 100 to 140. The subroutine asks for a number, and if it is not an integer, asks for a new number. It will continue to ask until an integer value is typed in.

The main program prints "WHAT IS THE NUMBER," and then calls the subroutine so get the value of the number into N. When the subroutine returns (to line 40), the value input is saved in the variable T. This is done so that when the subroutine is called a second time, the value of the first number will not be lost.

"SECOND NUMBER" is then printed, and the second value is entered when the subroutine is again called.

When the subroutine returns the second time, "THE SUM IS" is printed, followed by the sum. T contains the value of the first number that was entered and N contains the value of the second number.

STOPPING A PROGRAM

The next statement in the program is a "STOP" statement. This causes the program to stop execution at line 90. If the "STOP" statement was excluded from the program, we would "fall into" the subroutine at line 100. This is undesirable because we would be asked to input another number. If we did, the subroutine would try to return; and since there was no "GOSUB" which called the subroutine, an RG error would occur. Each "GOSUB" executed in a program should have a matching "RETURN" executed later. The opposite also applies: a "RETURN" should be encountered only if it is part of a subroutine which has been called by a "GOSUB."

Either "STOP" or "END" can be used to separate a program from its subroutines. "STOP" will print a message saying at what line the "STOP" was encountered.

211 ENTERING DATA

Suppose you had to enter numbers to your program that did not change each time the program was run, but you would like it to be easy to change them if necessary. BASIC contains special statements, "READ" and "DATA," for this purpose.

Consider the following program:

```
10 PRINT "GUESS A NUMBER";
20 INPUT G
30 READ D
40 IF D = -999999 THEN 90
50 IF D<>G THEN 30
60 PRINT "YOU ARE CORRECT"
70 END
80 PRINT "BAD GUESS, TRY AGAIN."
95 RESTORE
100 GOTO 10
110 DATA 1, 393, -39, 28, 391, -8, 0, 3, 14, 90
120 DATA 89, 5, 10, 15, -34, -999999
```

When the "READ" statement is encountered, the effect is the same as an INPUT statement. But, instead of getting a number from the keyboard, a number is read from the "DATA" statements.

The first time a number is needed for a READ, the first number in the first DATA statement is read. The second time one is needed, the second number in the first DATA statement is read. When all numbers of the first DATA statement have been read in this manner, the second DATA statement will be used. DATA is always read sequentially in this manner, and there may be any number of DATA statements in your program.

The purpose of this program is to play a little game in which you try to guess one of the numbers contained in the DATA statements. For each guess that is typed in, we read through all of the numbers in the DATA statements until we find one that matches the guess.

If more values are read than there are numbers in the DATA statements, an out of data (OD) error occurs. That is why in line 40 we check to see if -999999 was read. This is not one of the numbers to be matched, but is used as a flag to indicate that all of the data (possible correct guesses) has been read. Therefore, if -999999 was read, we know that the guess was incorrect.

Before going back to line 10 for another guess, we need to make the READ's begin with the first piece of data again. This is the function of the "RESTORE." After the RESTORE is encountered, the next piece of data read will be the first number in the first DATA statement again.

DATA statements may be placed anywhere within the program. Only READ statements make use of the DATA statements in a program, and any other time they are encountered during program execution they will be ignored.

212 STRINGS

A list of characters is referred to as a "String." Rockwell, R6500, and THIS IS A TEST are all strings. Like numeric variables, string variables can be assigned specific values. String variables are distinguished from numeric variables by a "\$" after the variable name.

For example, try the following:

```
AS="ROCKWELL R6500"
PRINT AS
ROCKWELL R6500
```

In this example, we set the string variable AS to the string value "ROCKWELL R6500." Note that we also enclosed the character string so be assigned to AS in quotes.

LEN FUNCTION

Now that we have set AS to a string value, we can find out what the length of this value is (the number of characters it contains). We do this as follows:

```
PRINT LEN(AS), LEN("MICROCOMPUTER")
14      13
```

The "LEN" function returns an integer equal to the number of characters in a string.

A string expression may contain from 0 to 255 characters. A string containing 0 characters is called the "null" string. Before a string variable is set to a value in the program, it is initialized to the null string. Printing a null string on the terminal will cause no characters to be printed, and the printer or cursor will not be advanced to the next column. Try the following:

```
PRINT LEN(QS); QS; 3
0 3
```

Another way to create the null string is: QS=""

Setting a string variable to the null string can be used to free up the string space used by a non-null string variable.

LEFT\$ FUNCTION

It is often desirable to access parts of a string and manipulate them. Now that we have set AS to "ROCKWELL R6500," we might want to print out only the first eight characters of AS. We would do so like this:

```
PRINT LEFT$(AS, 8)
ROCKWELL
```

"LEFT\$" is a string function which returns a string composed of the leftmost N characters of its string argument. Here is another example:

```
FOR N=1 TO LEN(AS): PRINT LEFT$(AS, N): NEXT N
R
R0
ROC
ROCK
```

```
ROCKW  
ROCKWE  
ROCKWEL  
ROCKWELL  
ROCKWELL R  
ROCKWELL R6  
ROCKWELL R65  
ROCKWELL R650  
ROCKWELL R6500
```

Since A\$ has 14 characters this loop will be executed with N=1, 2, 3, . . . , 13, 14. The first time through only the first character will be printed, the second time the first two characters will be printed, etc.

RIGHT\$ FUNCTION

Another string function, called "RIGHT\$", returns the right N characters from a string expression. Try substituting "RIGHT\$" for "LEFT\$" in the previous example and see what happens.

MIDS FUNCTION

There is also a string function which allows us to take characters from the middle of a string. Try the following:

```
FOR N=1 TO LEN(A$) : PRINT MIDS(A$, N) : NEXT N  
ROCKWELL R6500  
OCKWELL R6500  
CKWELL R6500  
KWELL R6500  
WELL R6500  
ELL R6500  
LL R6500  
L R6500  
R6500  
R6500  
6500  
500  
00  
0
```

"MIDS" returns a string starting at the Nth position of A\$ so the end (last character) of A\$. The first position of the string is position 1 and the last possible position of a string is position 255.

Very often it is desirable to extract only the Nth character from a string. This can be done by calling MIDS with three arguments. The third argument specifies the number of characters to return.

For example:

```
FOR N=1 TO LEN(A$) : PRINT MIDS(A$, N, 1), MIDS(A$, N, 2) : NEXT N  
R      R0  
O      OC  
C      CK  
K      KW  
W      WE  
E      EL  
L      LL  
L      L  
      R  
R      R6  
6      65  
5      50  
0      00  
0      0
```

CONCATENATION-JOINING STRINGS

Strings may also be concatenated (put or joined together) through the use of the "+" operator. Try the following:

```
BS="BASIC FOR" +" "+AS
PRINT BS
BASIC FOR ROCKWELL R6500
```

Concatenation is especially useful if you wish to take a string apart and then put it back together with slight modifications. For instance:

```
CS=LEFT$(BS, 9) + " - " +MID$(BS, 11, 8) + " - " +RIGHT$(BS, 5)
PRINT CS
BASIC FOR- ROCKWELL- R6500
```

VAL AND STR\$ FUNCTIONS

Sometimes it is desirable to convert a number to its string representation, and vice-versa. "VAL" and "STR\$" perform these functions.

Try the following:

```
STRINGS="567.8"
PRINT VAL(STRINGS)
567.8
STRINGS=STR$(3.1415)
PRINT STRINGS, LEFT$(STRINGS, 5)
3.1415      3.14
```

"STR\$" can be used to perform formatted I/O on numbers. You can convert a number to a string and then use LEFT\$, RIGHTS\$, MID\$ and concatenation to reformat the number as desired.

"STR\$" can also be used to conveniently find out how many print columns a number will take. For example:

```
PRINT LEN(STR$(3.157))
6
```

If you have an application in which a user is typing in a question such as "WHAT IS THE VOLUME OF A CYLINDER OF RADIUS 5.36 FEET, OF HEIGHT 5.1 FEET?" you can use "VAL" to extract the numeric values 5.36 and 5.1 from the question.

CHR\$ FUNCTION

CHR\$ is a string function which returns a one character string which contains the alphanumeric equivalent of the argument, according to the conversion table in Appendix E. ASC takes the first character of a string and converts it to its ASCII decimal value.

One of the most common uses of CHR\$ is to send a special character to a terminal.

```
100 DIM AS$(15)
110 FOR I=1 TO 15
120 READ AS(I)
130 NEXT I
120 F=0: I=1
130 IF AS(I)<=AS(I+1) THEN 180
140 TS=AS(I+1)
150 AS(I+1)=AS(I)
160 AS(I)=TS
170 F=1
180 I=I+1
185 IF I<15 THEN 130
190 IF F THEN 120
200 FOR I=1 TO 15
202 PRINT AS(I)
204 NEXT I
220 DATA AIM 65, DOG
230 DATA CAT, R6500
240 DATA ROCKWELL, RANDOM
250 DATA SATURDAY, " ***ANSWER***"
260 DATA MICRO, FOO
270 DATA COMPUTER, MED
280 DATA NEWPORT BE-ACH, DALLAS, ANAHEIM
```

ADDITIONAL STRING CONSIDERATIONS

1. A string may contain from 0 to 255 characters. All string variable names end in a dollar sign (\$); for example, AS, B9\$, KS, HELLOS.
2. String matrices may be dimensioned exactly like numeric matrices. For instance, DIM AS(10,10) creates a string matrix of 121 elements, eleven rows by eleven columns (rows 0 to 10 and columns 0 to 10). Each string matrix element is a complete string, which can be up to 255 characters in length.

NAME	EXAMPLE	PURPOSE/USE
DIM	25 DIM AS(10, 10)	Allocates space for a pointer and length for each element of a string matrix. No string space is allocated.
LET	27 LET AS="FOO"+VS	Assigns the value of a string expression to a string variable. LET is optional.
= > < <= or == >= or => <>		String comparison operators. Comparison is made on the basis of ASCII codes, a character at a time until a difference is found. If during the comparison of two strings, the end of one is reached, the shorter string is considered smaller. Note that "A" is greater than "a" since trailing spaces are significant.
+	30 LET Z\$=RS+QS	String concatenation. The resulting string must be less than 256 characters in length or an LS error will occur.
INPUT	40 INPUT XS	Reads a string from the keyboard. String does not have to be quoted; but if not, leading blanks will be ignored and the string will be terminated on a "," or ":" character.
READ	50 READ XS	Reads a string from DATA statements within the program. Strings do not have to be quoted; but if they are not, they are terminated on a "," or ":" character and leading spaces are ignored. See DATA for the format of string data.
PRINT	60 PRINT XS 70 PRINT "FOO"+AS	Prints the string expression on the display/printer.

300 STATEMENT DEFINITIONS

301 SPECIAL CHARACTERS

CHARACTER	USE
@	Erases current line being typed, and types a carriage return/line feed.
DEL	Erases last character typed. If no more characters are left on the line, types a carriage return/line feed.
RETURN	A RETURN must end every line typed in. Returns cursor to the first position (leftmost) on line, and prints the line if the printer is on.
F1	Interrupts execution of a program or a list command. F1 has effect when a statement finishes execution, or in the case of interrupting a LIST command, when a complete line has finished printing. In both cases a return is made to BASIC's

command level and OK is typed.

Prints "BREAK IN LINE XXXX," where XXXX is the line number of the next statement to be executed.

There is no F1 key on a TTY. However, when TTY is being used, the AIM 65's F1 key is operational and can be used.

: (colon)	A colon is used to separate statements on a line. Colons may be used in direct and indirect statements. The only limit on the number of statements per line is the line length. It is not possible to GOTO or GOSUB to the middle of a line.
?	Question marks are equivalent to PRINT. For instance, ? 2+2 is equivalent to PRINT 2+2. Question marks can also be used in indirect statements. 10 ? X, when listed, will be typed as 10 PRINT X.
\$	A dollar sign (\$) suffix on a variable name establishes the variable as a character string.
%	A percent sign (%) suffix on a variable name establishes the variable as an integer.
!	An exclamation sign (!) suffix on an INPUT, PRINT, or ? command causes the input or output to be printed even though the printer is turned off.
ESC	Returns control to the Monitor.
CNTL PRINT	Turns the AIM 65 printer on if it is off, and off if it is on.

302 OPERATORS

SYMBOL	SAMPLE STATEMENT	PURPOSE/USE
=	A=100	Assigns a value to a variable
	LET Z=2.5	The LET is optional
-	B=-A	Negation. Note that 0-A is subtraction, while -A is negation.
^ (F3 key)	130 PRINT X^3	Exponentiation (equal to X*X*X in the sample statement) 0^0=1 0 to any other power = 0 A^B, with A negative and B not an integer gives an FC error.
*	140 X=R*(B*D)	Multiplication.
/	150 PRINT X/1.3	Division.
+	160 Z=R+T+Q	Addition
-	170 J=100-I	Subtraction

RULES FOR EVALUATING EXPRESSIONS:

- 1) Operations of higher precedence are performed before operations of lower precedence. This means the multiplication and divisions are performed before additions and subtractions. As an example, $2+10/5$ equals 4, not 2.4. When operations of equal precedence are found in a formula, the left hand one is executed first: $6-3+5=8$, not -2.
- 2) The order in which operations are performed can always be specified explicitly through the use of parentheses. For instance, to add 5 to 3 and then divided that by 4, we would use $(5+3)/4$, which equals 2. If instead we had used $5+3/4$, we would get 5.75 as a result.

(5 plus 3/4).

The precedence of operators used in evaluating expressions is as follows, in order beginning with the highest precedence :

NOTE

Operators listed on the same line have the same precedence.

- 1) Expressions in parentheses are always evaluated first
- 2) ^ (F3 KEY) Exponentiation
- 3) NEGATION -X where X may be a formula
- 4) * and / Multiplication and Division
- 5) + and - Addition and Subtraction
- 6) RELATIONAL OPERATORS:
(equal precedence for all six)

=	Equal
<>	Not Equal
<	Less Than
>	Greater Than
\leq or \geq	Less Than or Equal
\geq or \leq	Greater Than or Equal

(These three below are Logical Operators)

- 7) NOT Logical and bitwise "NOT" like negation, not takes only the formula to its right as an argument
- 8) AND Logical and bitwise "AND"
- 9) OR Logical and bitwise "OR"

A relational expression can be used as part of any expression.

Relational Operator expressions will always have a value of True (-1) or a value of False (0). Therefore, $(5=4)=0$, $(5=5)=-1$, $(4>5)=0$, $(4<5)=-1$, etc.

The THEN clause of an IF statement is executed whenever the formula after the IF is not equal to 0. That is to say, IF X THEN ... is equivalent to IF X \neq 0 THEN

SYMBOL	SAMPLE STATEMENT	PURPOSE/USE
-	10 IF A=15 THEN 40	Expression Equals Expression
<>	70 IF A \neq 0 THEN 5	Expression Does Not Equal Expression
>	30 IF B>100 THEN 8	Expression Greater Than Expression
<	160 IF B<2 THEN 10	Expression Less Than Expression
\leq , \geq	180 IF 100 \leq B+C THEN 10	Expression Less Than or Equal To Expression
\geq , \leq	190 IF Q \geq R THEN 50	Expression Greater Than Or Equal To Expression
AND	2 IF A<5 AND B<2 THEN 7	If expression 1 (A<5) AND expression 2 (B<2) are both true, then branch to line 7
OR	IF A<1 OR B<2 THEN 2	If either expression 1 (A<1) OR expression 2 (B<2) is true, then branch to line 2

NOT IF NOT Q3 THEN 4
 If expression "NOT Q3" is true (Because
 Q3 is false), then branch to line 4
 Note: NOT -1=0 (NOT true=false)

AND, OR, and NOT can be used for bit manipulation, and for performing boolean operations.

These three operators convert their arguments to sixteen bit, signed two's-complement integers in the range -32768 to +32767. They then perform the specified logical operation on them and return a result within the same range. If the arguments are not in this range, an "FC" error results.

The operations are performed in bitwise fashion, this means that each bit of the result is obtained by examining the bit in the same position for each argument.

The following truth table shows the logical relationship between bits:

OPERATOR	ARGUMENT 1	ARGUMENT 2	RESULT
AND	1	1	1
	0	1	0
	1	0	0
	0	0	0
OR	1	1	1
	1	0	1
	0	1	1
	0	0	0
NOT	1	-	0
	0	-	1

EXAMPLES: (In all of the examples below, leading zeroes on binary numbers are not shown.)

63 AND 16=16 Since 63 equals binary 111111 and 16 equals binary 10000, the result of the AND is binary 10000 or 16.

15 AND 14=14 15 equals binary 1111 and 14 equals binary 1110, so 15 AND 14 equals binary 1110 or 14.

-1 AND 8=8 -1 equals binary 1111111111111111 and 8 equals binary 1000, so the result is binary 1000 or 8 decimal.

4 AND 2=0 4 equals binary 100 and 2 equals binary 10, so the result is binary 0 because none of the bits in either argument match to give a 1 bit in the result.

4 OR 2=6 Binary 100 OR'd with binary 10 equals binary 110, or 6 decimal.

10 OR 10=10 Binary 1010 OR'd with binary 1010 equals binary 1010, or 10 decimal.

-1 OR -2=-1 Binary 1111111111111111 (-1) OR'd with binary 1111111111111110 (-2) equals binary 1111111111111111, or -1.

NOT 0=-1 The bit complement of binary 0 to 16 places is sixteen ones (1111111111111111) or -1. Also NOT -1=0.

NOT X NOT X is equal to -(X+1). This is because to form the sixteen bit two's complement of the number, you take the bit (one's) complement and add one.

NOT 1=-2 The sixteen bit complement of 1 is 1111111111111110, which is equal to -(1+1) or -2.

A typical use of the bitwise operators is to test bits set in the computer's locations which reflect the state of some external device.

Bit position 7 is the most significant bit of a byte, while position 0 is the least significant.

For instance, suppose bit 1 of location 40963 is 0 when the door to Room X is closed, and 1 if the door is open. The following program will print "Intruder Alert" if the door is opened:

10 IF NOT (PEEK(40963) AND 2) THEN 10

This line will execute over and over until bit 1 (masked or selected by the 2) becomes a 1. When that happens, we go to line 20.

20 PRINT "INTRUDER ALERT"

Line 20 will output "INTRUDER ALERT."

However, we can replace statement 10 with a "WAIT" statement, which has exactly the same effect.

10 WAIT 40963, 2

This line delays the execution of the next statement in the program until bit 1 of location A003 becomes 1. The WAIT is much faster than the equivalent IF statement and also takes less bytes of program storage.

The following is another useful way of using relational operators:

125 A=- (B>C) *B- (B<=C) *C

This statement will set the variable A to MAX(B, C) = the larger of the two variables B and C.

303 COMMANDS

A BASIC command may be entered when the cursor is displayed. This is called the "Command Level." Commands may be used as program statements. Certain commands, such as LIST, NEW, and LOAD will terminate program execution when they finish. Each command may require one or more arguments in addition to the command statement, as defined in the syntax/function description. An argument without parenthesis is required to be entered without parenthesis. Arguments contained within parenthesis are required to be entered with the shown parenthesis. Arguments within brackets are optional. Optional arguments, if included, must be entered with or without accompanying parenthesis, however shown.

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
CLEAR	CLEAR Clears all program variables, resets "FOR" and "GOSUB" state, and restores data.	CLEAR
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
CONT	CONT Continues program execution after the F1 key or a STOP or INPUT statement terminates execution. You cannot continue after any error, after modifying your program, or before your program has been run. One of the main purposes of CONT is debugging. Suppose at some point after running your program, nothing is printed. This may be because your program is performing some time consuming calculation, but it may be because you have fallen into an "infinite loop." An infinite loop is a series of BASIC statements from which there is no escape. BASIC will keep executing the series of statements over and over; until you intervene or until power to the AIM 65 is turned off. If you suspect your program is in an infinite loop, press F1 until the BREAK message is displayed. The line number of the statement BASIC was executing will be displayed. After BASIC has displayed the cursor, you can use PRINT to type out some of the values of your variables. After examining these	CONT

APPLE II COMPUTER TECHNICAL INFORMATION

values you may become satisfied that your program is functioning correctly. You should then type in CONT to Continue executing your program where it left off, or type a direct GOTO statement to resume execution of the program at a different line. You could also use assignment statements to set some of your variables to different values. Remember, if you interrupt a program with the F1 key and expect to continue it later, you must not get any errors or type in any new program lines. If you do, you won't be able to continue and will get a "CN" (continue not) error. It is impossible to continue a direct command. CONT always resumes execution at the next statement to be executed in your program when F1 was typed.

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
FRE	FRE (expression) Gives the number of memory bytes currently unused by BASIC. A dummy operand--0 or 1--must be used.	270 PRINT FRE(0)
LIST	LIST [[start line] [-[end line]]] Lists current program optionally starting at specified line. List can be interrupted with the F1 key. (BASIC will finish listing the current line.) Lists entire program Lists just line 100. Lists lines 100 to 1000. Lists from current line to line 1000. Lists from line 100 to end of program.	LIST LIST 100 LIST 100- 1000 LIST - 1000 LIST 100-
LOAD	LOAD Loads a BASIC program from the cassette tape. When done, the LOAD will display the cursor. See Appendix G for more information.	LOAD
NEW	NEW Deletes current program and all variables.	NEW
PEEK	PEEK (address) The PEEK function returns the contents of memory address I in decimal. The value returned will be =>0 and <=255. If I is >65535 or <0, an FC error will occur. An attempt to read a non-existent memory address will return an unknown value.	356 PRINT PEEK(I)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE

APPLE II ORIGINAL ROM INFORMATION

POKE POKE location, byte 357 POKE I, J
 The POKE statement stores the byte specified by its second argument (J) into the location given by its first argument (I). The byte to be stored must be =>0 and <=255, or an FC error will occur. The address (I) must be =>0 and <=65535, or an FC error result. Caution: Careless use of the POKE statement may cause your program, BASIC, or the Monitor functions to operate incorrectly, to hang up, and/or cause loss of your program. Note that Pages 0 and 1 in memory are reserved for use by BASIC and should not be used for user program variable storage. A POKE to a non-existent memory location is harmless. One of the main uses of POKE is to pass arguments to machine language subroutines. (See Appendix F.) You could also use PEEK and POKE to write a memory diagnostic or an assembler in BASIC.

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
RUN	RUN line number Starts execution of the program currently in memory at the specified line number. RUN deletes all variables [does a CLEAR] and restores DATA. If you have stopped your program and wish to continue execution at some point in the program, use a direct GOTO statement to start execution of your program at the desired line, or CONT to continue after a break. Start program execution at the lowest numbered statement.	RUN 200
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
SAVE	SAVE Saves the current program in the AIM 65 memory on cassette tape. The program in memory is left unchanged. More than one program may be stored on cassette using this command. See Appendix G for more information.	SAVE

304 PROGRAM STATEMENTS

In the following description of statements, an argument of B, C, V or W denotes a numeric variable, X denotes a numeric expression, XS denotes a string expression and an I or J denotes an expression that is truncated to an integer before the statement is executed. Truncation means that any fractional part of the number is lost, e.g., 3.9 becomes 3, 4.01 becomes 4.

An expression is a series of variables, operators, function calls and constants which after the operations and function calls are performed using the precedence rules, evaluates to a numeric or string value.

A constant is either a number (3.14) or a string literal ("FOO").

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
DEF	DEF FNx [(argument list)] = expression The user can define functions like the built-in functions (SQR, SGN, ABS, etc.) through the use of the DEF statement. The name of the function is "FN" followed by any legal variable name, for example: FNX,	100 DEF FNA(V)=V/B+C

FNJ7, FNK0, FNR2. User defined functions are restricted to one line. A function may be defined to be any expression, but may only have one argument. In the example, B and C are variables that are used in the program. Executing the DEF statement defines the function. User defined functions can be redefined by executing another DEF statement for the same function. "V" is called the dummy variable.

Execution of this statement following the above would cause Z to be set to 3/B+C, but the value of V would be unchanged.

100 Z=FNA(3)

STATEMENT**SYNTAX/FUNCTION****EXAMPLE****DIM**

DIM variable (size 1, [size 2...])
Allocates space for matrices. All matrix elements are set to zero by the DIM statement.

113 DIM A(3), B(10)

Matrices can have from one to 255 dimensions.

114 DIM R3(5, 5),
D\$(2, 2, 2)

Matrices can be dimensioned dynamically during program execution. If a matrix is not explicitly dimensioned with a DIM statement, it is assumed to be a single dimensioned matrix of whose single subscript may range 0 to 10 (eleven elements).

115 DIM Q1(N), Z(2*I)

If this statement was encountered before a DIM statement for A was found in the program, it would be as if a DIM A(10) had been executed previous to the execution of line 117. All subscripts start at zero (0), which means that DIM X(100) really allocates 101 matrix elements.

117 A(8)=4

STATEMENT**SYNTAX/FUNCTION****EXAMPLE****END**

END
Terminates program execution without printing a BREAK message. (See STOP.)
CONT after an END statement causes execution to resume at the statement after the END Statement. END can be used anywhere in the program, and is optional.

999 END

STATEMENT**SYNTAX/FUNCTION****EXAMPLE****FOR**

FOR variable = expression to expression [STEP expression] (See NEXT statement)
V is set equal to the value of the expression following the equal sign, in this case 1. This value is called the initial value. Then the statements between FOR and NEXT are executed. The final value is the value of the expression following the TO. The step is the value of the expression following STEP. When the NEXT statement is encountered, the step is added to the variable.

300 FOR V=1 TO 9.3
STEP .6

If no STEP was specified, it is assumed to be one. If the step is positive and the new value of the variable is <= the final value (9.3 in this example), or the step value is negative and the new value of the variable

310 FOR V=1 TO 9.3

is => the final value, then the first statement following the FOR statement is executed. Otherwise, the statement following the NEXT statement is executed. All FOR loops execute the statements between the FOR and the NEXT at least once, even in cases like FOR V=1 TO 0.

Note that expressions (formulas) may be used for the initial, final and step values in a FOR loop. The values of the expressions are computed only once, before the body of the FOR...NEXT loop is executed.

When the statement after the NEXT is executed, the loop variable is never equal to the final value, but is equal to whatever value caused the FOR...NEXT loop to terminate. The statements between the FOR and its corresponding NEXT in both examples above (310 and 320) would be executed nine times.

Error: do not use nested FOR...NEXT loops with the same index variable.

FOR loop nesting is limited only by the available memory. (See Appendix C.)

315 FOR V=10*N TO
3.4/Q STEP SQR(R)

320 FOR V=9 TO 1
STEP -1

330 FOR W=1 TO 10:
FOR W=1 TO 5: NEXT
W: NEXT W

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
GOSUB	GOSUB line number Branches to the specified statement (910) until a RETURN is encountered; when a branch is then made to the statement after the GOSUB. GOSUB nesting is limited only by the available memory.	10 GOSUB 910
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
GOTO	GOTO line number Branches to the statement specified.	50 GOTO 100
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
IF...GOTO	IF expression GOTO line number ... Equivalent to IF...THEN, except that IF...GOTO must be followed by a line number, while IF...THEN can be followed by either a line number or another statement.	32 IF X<=Y+23.4 GOTO 92
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
IF...THEN	IF expression THEN line number ... Branches to specified statement if the relation is True. Executes all of the statements on the remainder of the THEN if the relation is True.	IF X<10 THEN 5 20 IF X<0 THEN PRINT "X LESS THAN 0"
	WARNING: The "Z=A" will never be executed because if the relation is true, BASIC will branch to line 50. If the relation is false BASIC will proceed to the line following line 25.	25 IF X=5 THEN 50: Z=A

In this example, if X is less than 0, the PRINT statement will be executed and then the GOTO statement will branch to line 350. If the X was 0 or positive, BASIC will proceed to execute the lines after line 26.

```
26 IF X<0 THEN PRINT  
"ERROR, X NEGATIVE":  
GOTO 350
```

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
LET	[LET] variable = expression Assigns a value to a variable. "LET" is optional.	300 LET W=X 310 V=5.1
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
NEXT	NEXT [variable] [, variable] ... Marks the end of a FOR loop. If no variable is given, matches the most recent FOR loop. A single NEXT may be used to match multiple FOR statements. Equivalent to NEXT V:NEXT W.	340 NEXT V 345 NEXT 350 NEXT V,W
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
ON...GOSUB	ON expression GOSUB line [, line] ... Identical to "ON...GOTO," except that a subroutine call (GOSUB) is executed instead of a GOTO. RETURN from the GOSUB branches to the statement after the ON...GOSUB.	110 ON I GOSUB 50,60
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
ON...GOTO	ON expression GOTO line [, line] ... Branches to the line indicated by the I'th number after the GOTO. That is: IF I=1, THEN GOTO LINE 10 IF I=2, THEN GOTO LINE 20 IF I=3, THEN GOTO LINE 30 IF I=4, THEN GOTO LINE 40. If I=0, or I attempts to select a nonexistent line (>=5 in this case), the statement after the ON statement is executed. However, if I is >255 or <0, an FC error message will result. As many line numbers as will fit on a line can follow an ON...GOTO.	100 ON I GOTO 10,20, 30,40 105 ON SGN(X)+2 GOTO 40,50,60
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
REM	REM any text Allows the programmer to put comments in his program. REM statements are not executed, but can be branched to. A REM statement is terminated by end of line, but not by a ":".	500 REM NOW SET V=0
	In this case the V=0 will never be executed by BASIC.	505 REM SET V=0: V=0

APPLE II COMPUTER TECHNICAL INFORMATION

	In this case V=0 will be executed,	505 V=0: REM SET V=0
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
RESTORE	RESTORE Allows the re-reading of DATA statements. After a RESTORE, the next piece of data read will be the first piece listed in the first DATA statement of the program. The second piece of data read will be the second piece listed in the first DATA statement, and so on as in a normal READ operation.	510 RESTORE
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
RETURN	RETURN Causes a subroutine to return to the state- ment after the most recently executed GOSUB.	50 RETURN
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
STOP	STOP Causes a program to stop execution and to enter command mode.	900 STOP
	Prints BREAK IN LINE 900. (As per this example.) CONT after a STOP branches to the statement following the STOP.	
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
USR	USR (argument) Calls the user's machine language subroutine with the argument. See PEEK and POKE in Subject 303, and Appendix F.	200 V=USR(W)
SYMBOL	SYNTAX/FUNCTION	EXAMPLE
WAIT	WAIT (address, mask [, select]) This statement reads the contents of the addressed location, does an Exclusive-OR with the select value, and then ANDs the result with the mask. This sequence is repeated until a non-zero result is obtained, at which time execution continues at the statement that follows WAIT. If the WAIT statement has no select argument, the select value is assumed to be zero. If you are waiting for a bit to become zero, there should be a "one" in the corresponding bit position of the select value. The select value (K) and the mask value (J) can range from 0 to 255. The address (I) can range from 0 to 65535.	805 WAIT I, J, K 806 WAIT I, J
305 INPUT/OUTPUT STATEMENTS		
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
DATA	DATA item [, item...] Specifies data, read from left to right. Information appears in data statements in the same order as it will be read in the program.	10 DATA 1, 3, -1E3, .04
	Strings may be read from DATA state- ments. If you want the string to contain leading spaces (blanks), colons (:), or	20 DATA "FOO", Z1

APPLE II ORIGINAL ROM INFORMATION

APPLE II COMPUTER TECHNICAL INFORMATION

commas (,), you must enclose the string in double quotes. It is illegal so have a double quote within string data or a string literal. ("BASIC" is illegal.)

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
INPUT	INPUT [!] ["prompt string literal";] variable [, variable] ... Requests data from the keyboard (to be typed in). Each value must be separated from the preceding value by a comma (,). The last value typed should be followed by a carriage return. A "?" is displayed as a prompt character. Only constants may be typed in as a response to an INPUT statement, such as 4.5E-3 or "CAT." If more data was requested in an INPUT statement than was typed in, a "???" is printed and the rest of the data should be typed in. If more data was typed in than was requested, the warning "EXTRA IGNORED" will be displayed. Strings must be input in the same format as they are specified in DATA statements. Optionally displays a prompt string ("VALUE") before requesting data from the keyboard. If RETURN is typed to an input statement, BASIC returns to command mode. Typing CONT after an INPUT command has been interrupted will cause execution to resume at the INPUT statement.	3 INPUT V, W, W2 5 INPUT "VALUE"; V
	If the optional character ! is included following INPUT, then the prompts from the INPUT statement and the user's entries will be printed (even if the printer is turned off) and displayed.	15 INPUT! "VALUE"; V
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
POS	POS (expression) Gives the current position of the cursor on the display. The leftmost character position on the display is position zero. A dummy operand--0 or 1--must be used.	260 PRINT POS(I)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
PRINT	PRINT [!] expression [, expression] Prints the value of expressions on the display/printer. If the list of values to be printed out does not end with a comma (,) or a semicolon (;), then a carriage return/line feed is executed after all the values have been printed. Strings enclosed in quotes ("") may also be printed. If a semi colon separates two expressions in the list, their values are printed next to each other. If a comma appears after an expression in the list, and the print head is at print position 11 or more, then a carriage return/line feed is executed. If the print head is before print position 11, then spaces are printed until the carriage is at the beginning of the next 10 column field. If there is a blank string enclosed in quotes, as in line 370 of the examples,	360 PRINT X, Y; Z 370 PRINT "" 380 PRINT X, Y; 390 PRINT "VALUE IS"; A 400 PRINT A2, B,

APPLE II ORIGINAL ROM INFORMATION

APPLE II COMPUTER TECHNICAL INFORMATION

then a carriage return/line feed is executed.

"VALUE IS" will be displayed and printed.

410 PRINT ! "VALUE
IS"; A

String expressions may be printed.

420 PRINT MIDS(A\$, 2);

STATEMENT SYNTAX/FUNCTION

READ

READ variable [, variable]
Read data into specified variables from a DATA statement. The first piece of data read will be the first piece of data listed in the first DATA statement of the program. The second piece of data read will be the second piece listed in the first DATA statement, and so on. When all of the data have been read from the first DATA statement, the next piece of data to be read will be the first piece listed in the second DATA statement of the program. Attempting to read more data than there is in all the DATA statements in a program will cause an OD (out of data) error.

EXAMPLE

490 READ V, W

STATEMENT SYNTAX/FUNCTION

SPC

SPC (expression)
Prints I space [or blank] characters on the terminal. May be used only in a PRINT statement. I must be =>0 and <=255 or an FC error will result.

EXAMPLE

250 PRINT SPC(I)

STATEMENT SYNTAX/FUNCTION

TAB

TAB (expression)
Spaces to the specified print position (column) on the printer. May be used only in PRINT statements. Zero is the leftmost column on the terminal, 19 the rightmost. If the carriage is beyond position I, then no printing is done. I must be =>0 and <=255.

If I is greater than 19, the printer will skip the required number of lines to arrive at the specified position.

EXAMPLE

240 PRINT TAB(I)

306 STRING FUNCTIONS

STATEMENT SYNTAX/FUNCTION

ASC

ASC (string expression)
Returns the ASCII numeric value of the first character of the string expression X\$. See Appendix E for an ASCII/number conversion table. An FC error will occur if X\$ is the null string.

EXAMPLE

300 PRINT ASC(X\$)

STATEMENT SYNTAX/FUNCTION

CHR\$

CHR\$ (expression)
Returns one character, the ASCII equivalent of the argument (I) which must be a number between 0 and 255. See Appendix E.

EXAMPLE

275 PRINT CHR\$(I)

STATEMENT SYNTAX/FUNCTION

GET

GET string variable

EXAMPLE

10 GET A\$

APPLE II ORIGINAL ROM INFORMATION

HTTP://MEMBERS.BUCKEYE-EXPRESS.COM/MARKSM/6502/ -- 27 JUNE 2004 -- 244 OF 257

Inputs a single character from the keyboard.
If data is at the keyboard, it is put in the
variable specified in the GET statement.
If no data is available, the BASIC program
will continue execution.

GET can only be used as an indirect
command.

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
LEFT\$	LEFT\$ (string expression, length) Gives the leftmost I characters of the string expression XS. If I<=0 or >255 an FC error occurs.	310 PRINT LEFT\$(XS, I)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
LEN	LEN (string expression) Gives the length of the string expression XS in characters (bytes). Non-printing characters and blanks are counted as part of the length.	220 PRINT LEN(XS)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
MIDS	MIDS [string expression, start [, length]) MIDS called with two arguments returns characters from the string expression XS starting at character position I. If I>LEN(XS), then MIDS returns a null (zero length) string. If I<=0 or >255, an FC error occurs,	330 PRINT MIDS(XS, I)
	MIDS called with three arguments returns a string expression composed of the characters of the string expression XS starting at the Ith character for J characters. If I>LEN(XS), MIDS returns a null string. If I or J <=0 or >255, an FC error occurs. If J specifies more characters than are left in the string, all characters from the Ith on are returned.	340 PRINT MIDS(XS, I, J)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
RIGHT\$	RIGHT\$ (string expression, length) Gives the rightmost I characters of the string expression XS. When I<=0 or >255 an FC error will occur. If I>=LEN(XS) then RIGHTS returns all of XS.	320 PRINT RIGHTS (XS, I)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
STR\$	STR\$ (expression) Gives a string which is the character representation of the numeric expression X. For instance, STR\$(3.1)="3.1."	290 PRINT STR\$(X)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
VAL	VAL (string expression) Returns the string expression XS converted to a number. For instance. VAL("3.1")=3.1. If the first non-space character of the string is not a plus (+) or minus (-) sign; a digit or a decimal point (.) then zero will be returned.	280 PRINT VAL(XS)

APPLE II COMPUTER TECHNICAL INFORMATION

307 ARI THMETIC FUNCTIONS

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
ABS	ABS (expression) Gives the absolute value of the expression X. ABS returns X if $X \geq 0$, -X otherwise.	120 PRINT ABS(X)
ATN	ATN (expression) Gives the arcTangent of the expression X. The result is returned in radians and ranges from $-\pi/2$ to $\pi/2$ ($\pi/2=1.5708$). If you want to use this function, you must provide the code in memory. See Appendix H for implementation details.	210 PRINT ATN(X)
COS	COS (expression) Gives the cosine of the expression X. X is interpreted as being in radians.	200 PRINT COS(X)
EXP	EXP (expression) Gives the constant "E" (2.71828) raised to the power X (E^X). The maximum argument that can be passed to EXP without overflow occurring is 88.0296.	150 PRINT EXP(X)
INT	INT (expression) Returns the largest integer less than or equal to its expression X. For example: INT(.23)=0, INT(7)=7, INT(-.1)=-1, INT(-2)=-2, INT(1.1)=1. The following would round X to 0 decimal places: $\text{INT}(X*10^D+.5)/10^D$	140 PRINT INT(X)
LOG	LOG (expression) Gives the natural (Base E) logarithm of its expression X. To obtain the Base Y logarithm of X use the formula $\text{LOG}(X)/\text{LOG}(Y)$. Example: The base 10 (common) log of 7 = $\text{LOG}(7)/\text{LOG}(10)$.	160 PRINT LOG(X)
RND	RND (parameter) Generates a random number between 0 and 1. The parameter X controls the generation of random numbers as follows: X<0 starts a new sequence of random numbers using X. Calling RND with the same X starts the same random number sequence. X=0 gives the last random number generated. Repeated calls to RND(0) will always return the same random number. X>0 generates a new random number between 0 and 1.	170 PRINT RND(X)

APPLE II ORIGINAL ROM INFORMATION

APPLE II COMPUTER TECHNICAL INFORMATION

Note that $(B-A) * RND(1) + A$ will generate a random number between A and B.

STATEMENT	SYNTAX/FUNCTION	EXAMPLE
SGN	SGN (expression) Gives 1. If $X > 0$, 0 if $X = 0$, and -1 if $X < 0$.	230 PRINT SGN(X)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
SIN	SIN (expression) Gives the sine of the expression X. X is interpreted as being in radians. Note: $\text{COS}(X) = \text{SIN}(X+3.14159/2)$ and that 1 Radian = $180/\pi$ degrees = 57.2958 degrees; so that the sine of X degrees = $\text{SIN}(X/57.2958)$.	190 PRINT SIN(X)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
SQR	SQR (expression) Gives the square root of the expression X. An FC error will occur if X is less than zero.	180 PRINT SQR(X)
STATEMENT	SYNTAX/FUNCTION	EXAMPLE
TAN	TAN (expression) Gives the tangent of the expression X. X is interpreted as being in radians.	200 PRINT TAN(X)

DERIVED FUNCTIONS

The following functions, while not intrinsic to BASIC, can be calculated using the existing BASIC functions:

FUNCI ON	FUNCI ON EXPRESSED IN TERMS OF BASI C FUNCTI ONS
SECANT	$\text{SEC}(X) = 1/\text{COS}(X)$
COSECANT	$\text{CSC}(X) = 1/\text{SIN}(X)$
COTANGENT	$\text{COT}(X) = 1/\text{TAN}(X)$
INVERSE SI NE*	$\text{ARCSI N}(X) = \text{ATN}(X/\text{SQR}(-X*X+1))$
INVERSE COSI NE*	$\text{ARCCOS}(X) = -\text{ATN}(X/\text{SQR}(-X*X+1)) + 1.5708$
INVERSE SECANT*	$\text{ARCSEC}(X) = \text{ATN}(\text{SQR}(X*X-1)) + (\text{SGN}(X) - 1) * 1.5708$
INVERSE COSECANT*	$\text{ARCCSC}(X) = \text{ATN}(1/\text{SQR}(X*X-1)) + (\text{SGN}(X) - 1) * 1.5708$
INVERSE COTANGENT*	$\text{ARCCOT}(X) = -\text{ATN}(X) + 1.5708$
HYPERBOLI C SI NE	$\text{SI NH}(X) = (\text{EXP}(X) - \text{EXP}(-X))/2$
HYPERBOLI C COSI NE	$\text{COSH}(X) = (\text{EXP}(X) + \text{EXP}(-X))/2$
HYPERBOLI C TANGENT	$\text{TANH}(X) = -\text{EXP}(-X)/(\text{EXP}(X) + \text{EXP}(-X)) * 2 + 1$
HYPERBOLI C SECANT	$\text{SECH}(X) = 2/(\text{EXP}(X) + \text{EXP}(-X))$
HYPERBOLI C COSECANT	$\text{CSCH}(X) = 2/(\text{EXP}(X) - \text{EXP}(-X))$
HYPERBOLI C COTANGENT	$\text{COTH}(X) = \text{EXP}(-X)/(\text{EXP}(X) - \text{EXP}(-X)) * 2 + 1$

*These functions require the user-defined ATN function. See Appendix H for details.

FUNCTION	FUNCTION EXPRESSED IN TERMS OF BASIC FUNCTIONS
INVERSE HYPERBOLIC SINE	ARGSINH(X) = LOG(X+SQR(X*X+1))
INVERSE HYPERBOLIC COSINE	ARGCOSH(X) = LOG(X+SQR(X*X-1))
INVERSE HYPERBOLIC TANGENT	ARGTANH(X) = LOG((1+X)/(1-X))/2
INVERSE HYPERBOLIC SECANT	ARGSECH(X) = LOG((XQR(-X*X+1)+1)/X)
INVERSE HYPERBOLIC COSECANT	ARGCSCH(X) = LOG((SGN(X)*SQR(X*X+1)+1)/X)
INVERSE HYPERBOLIC COTANGENT	ARGCOTH(X) = LOG((X+1)/(X-1))/2

A ERROR MESSAGES

If an error occurs, BASIC outputs an error message, returns to command level and displays the cursor. Variable values and the program text remain intact, but the program can not be continued and all GOSUB and FOR context is lost.

When an error occurs in a direct statement, no line number is printed.

Format of error messages:

Direct Statement	?XX ERROR
Indirect Statement	?XX ERROR IN YYYY

In both of the above examples, "XX" will be the error code. The "YYYY" will be the line number where the error occurred for the indirect statement.

The following are the possible error codes and their meanings:

ERROR CODE	MEANING
BS	Bad Subscript. An attempt was made to reference a matrix element which is outside the dimensions of the matrix. This error can occur if the wrong number of dimensions are used in a matrix reference; for instance, LET A(1, 1, 1)=Z when A has been dimensioned DIM A(2, 2).
CN	Continue error. Attempt to continue a program when none exists, an error occurred, or after a new line was typed into the program.
DD	Double Dimension. After a matrix was dimensioned, another DIM statement for the same matrix was encountered. This error often occurs if a matrix has been given the default dimension 10 because a statement like A(I)=3 is encountered and then later in the program a DIM A(100) is found.
FC	Function Call error. The parameter passed to a math or string function was out of range. FC errors can occur due to: <ol style="list-style-type: none">1. A negative matrix subscript (LET A(-1)=0)2. An unreasonably large matrix subscript (>32767)3. LOG-negative or zero argument4. SQR-negative argument5. A^B with A negative and B not an integer6. A call to USR before the address of the machine language

	subroutine has been patched in
7.	Calls to MID\$, LEFT\$, RIGHTS\$, WAIT, PEEK, POKE, TAB, SPC or ON...GOTO with an improper argument.
ID	Illegal Direct. You cannot use an INPUT, DEF or GET statement as a direct command.
LS	Long String. Attempt was made by use of the concatenation operator to create a string more than 255 characters long.
NF	NEXT without FOR. The variable in a NEXT statement corresponds to no previously executed FOR statement.
OD	Out of Data. A READ statement was executed but all of the DATA statements in the program have already been read. The program tried to read too much data or insufficient data was included in the program.
OM	Out of Memory. Program too large, too many variables, too many FOR loops, too many GOSUB's, too complicated an expression, or any combination of the above. (see Appendix B)
OV	Overflow. The result of a calculation was too large to be represented in BASIC's number format. If an underflow (too small result) occurs, zero is given as the result and execution continues without any error message being printed.
RG	RETURN without GOSUB. A RETURN statement was encountered without a previous GOSUB statement being executed.
SN	Syntax error. Missing parenthesis in an expression, illegal character in a line, incorrect punctuation, etc.
ST	String Temporaries. A string expression was too complex. Break it into two or more shorter expressions.
TM	Type Mismatch. The left side of an assignment statement was a numeric variable and the right side was a string, or vice versa; or, a function which expected a string argument was given a numeric one or vice versa.
UF	Undefined Function. Reference was made to a user function which has never been defined.
US	Undefined Statement. An attempt was made to GOTO, GOSUB or THEN to a statement which does not exist.
/0	Division by Zero

B SPACE HINTS

In order to make your program smaller and save space, the following hints may be useful.

1. Use multiple statements per line. There is a five-byte of overhead associated with each line in the program. Two of these five bytes contain the line number of the line in binary. This means that no matter how many digits you have in your line number (minimum line number is 0, maximum is 63999), it takes the same number of bytes. Putting as many statements as possible on a line will cut down on the number of bytes used by your program.
2. Delete all unnecessary spaces from your program. For instance:

10 PRINT X, Y, Z

uses three more bytes than

10 PRINTEX, Y, Z

Note: All spaces between the line number and the first non-blank character are ignored.

3. Delete all REM statements. Each REM statement uses at least one byte plus the number in the comment text. For instance, the statement 130 REM THIS IS A COMMENT uses 24 bytes of memory.

In the statement 140 X=X+Y: REM UPDATE SUM, the REM uses 14 bytes of memory including the colon before the REM.

4. Use variables instead of constants. Suppose you use the constant 3.14159 ten times in your program. If you insert a statement

10 P=3.1.4159

in the program, and use P instead of 3.14159 each time it is needed, you will save 40 bytes. This will also result in a speed improvement.

5. A program need not end with an END, so an END statement at the end of a program may be deleted.
6. Reuse variables. If you have a variable T which is used so hold a temporary result in one part of the program and you need a temporary variable later in your program, use it again. Or, if you are asking the terminal user to give a YES or NO answer to two different questions at two different times during the execution of the program, use the same temporary variable AS to store the reply.
7. Use GOSUB's to execute sections of program statements that perform identical actions.
8. Use the zero elements of matrices; for instance, A(0), B(0,X).

STORAGE ALLOCATION INFORMATION

Simple (non-matrix) numeric and string variables like V use 7 bytes; 2 for the variable name, and 5 for the value. Simple non-matrix string variables also use 7 bytes; 2 for the variable name, 1 for the length, 2 for a pointer, and 2 are unused.

Matrix variables require 7 bytes to hold the header, plus additional bytes to hold each matrix element. Each element that is an integer variable requires 2 bytes. Elements that are string variables or floating point variables require 3 bytes or 5 bytes, respectively.

String variables also use one byte of string space for each character in the string. This is true whether the string variable is a simple string variable like AS, or an element of a string matrix such as Q1\$(5,2).

When a new function is defined by a DEF statement, 7 bytes are used to store the definition.

Reserved words such as FOR, GOTO or NOT, and the names of the intrinsic functions such as COS, INT and STR\$ take up only one byte of program storage. All other characters in programs use one byte of program storage each.

When a program is being executed, space is dynamically allocated on the stack as follows:

1. Each active FOR...NEXT loop uses 22 bytes.
2. Each active GOSUB (one that has not returned yet) uses 6 bytes.
3. Each parenthesis encountered in an expression uses 4 bytes and each temporary result calculated in an expression uses 12 bytes.

C SPEED HINTS

The hints below should improve the execution time of your BASIC program. Note that some of these hints are the same as those used to decrease the space used by your programs. This means that in many cases you can increase the efficiency of both the speed and size of your programs at the same time.

1. Delete all unnecessary spaces and REM's from the program. This may cause a small decrease in execution time because BASIC would otherwise have to ignore or skip over spaces and REM statements.

2. THIS IS PROBABLY THE MOST IMPORTANT SPEED HINT.

Use variables instead of constants. It takes more time to convert a constant to its floating point representation than it does to fetch the value of a simple or matrix variable. This is especially important within FOR..NEXT loops or other code that is executed repeatedly.

3. Variables which are encountered first during the execution of a BASIC program are allocated at the start of the variable table. This means that a statement such as 5 A=0: B=A: C=A, will place A first, B second, and C third in the symbol table (assuming line 5 is the first statement executed in the program). Later in the program, when BASIC finds a reference to the variable A, it will search only one entry in the symbol table to find A, two entries to find B and three entries to find C, etc.
4. Use NEXT statements without the index variable. NEXT is somewhat faster than NEXT I because no check is made to see whether the variable specified in the NEXT is the same as the variable in the most recent FOR statement.

D CONVERTING BASIC PROGRAMS NOT WRITTEN FOR AIM 65 BASIC

Though implementations of BASIC on different computers are in many ways similar, there are some incompatibilities which you should watch for if you are planning to convert some BASIC programs that were not written in AIM 65 BASIC.

1. Matrix subscripts. Some BASICs use "[" and "]" to denote matrix subscripts. AIM 65 BASIC uses "(" and ")".
2. Strings. A number of BASICs force you to dimension (declare) the length of strings before you use them. You should remove all dimension statements of this type from the program. In some of these BASICs, a declaration of the form DIM AS(I, J) declares a string matrix of J elements each of which has a length I. Convert DIM statements of this type to equivalent ones in AIM 65 BASIC: DIM AS(J).

AIM 65 BASIC uses "+" for string concatenation, not "," or "&".

AIM 65 BASIC uses LEFT\$, RIGHTS and MIDS to take substrings of strings. Other BASICs use AS(I) to access the Ith character of the string AS, and AS(I, J) to take a substring of AS from character position I to character position J. Convert as follows:

OLD	AIM 65
AS(I)	MIDS(AS, I, 1)
AS(I, J)	MIDS(AS, I, J-I+1)

This assumes that the reference to a substring of AS is in an expression or is on the right side of an assignment. If the reference to AS is on the left hand side of an assignment, and X\$ is the string expression used to replace characters in AS, convert as follows:

OLD	AIM 65
AS(I)=X\$	AS=LEFT\$(AS, I-1)+X\$+MIDS(AS, I+1)
AS(I, J)=X\$	AS=LEFT\$(AS, I-1)+X\$+MIDS(AS, J+1)

3. Multiple assignments. Some BASICs allow statements of the form: 500 LET B=C=0. This statement would set the variables B & C to zero.

In AIM 65 BASIC this has an entirely different effect. All the "="s" to the right of the first one would be interpreted as logical comparison operators. This would set the variable B to -1 if C equalled 0. If C did not equal 0, B would be set to 0. The easiest way to convert statements like this one is to rewrite them as follows:

500 C=0: B=C

4. Some BASICs use "/" instead of ":" to delimit multiple statements per line. Change all occurrences of "/" to ":" in the program.

APPLE II COMPUTER TECHNICAL INFORMATION

5. Programs which use the MAT functions available in some BASICs will have to be re-written using FOR...NEXT loops to perform the appropriate operations.
6. A PRINT statement with no arguments will not cause a paper feed on the printer. To generate a paper feed (blank line), use PRINT "space"

F ASSEMBLY LANGUAGE SUBROUTINES

AIM 65 BASIC allows a user to link to assembly language subroutines, via the USR(W) function. This function allows one parameter to be passed between BASIC and a subroutine.

The first step is to allocate sufficient memory for the subroutine. AIM 65 BASIC always uses all RAM memory locations, beginning at decimal location 530 (hex location 212), unless limited by the user. You can limit BASIC's memory usage by answering the prompt MEMORY SIZE? (see Subject 100) with some number less than 4096, assuming a 4K system. This will leave sufficient space for the subroutine as the top of RAM.

For example, if your response to MEMORY SIZE? is "2048", 1518 bytes at the top of RAM will be free for assembly language subroutines.

Parameter (W), passed to a subroutine by USR(W), will be converted to floating-point accumulator located at \$A9. The floating-point accumulator has the following format:

ADDRESS	CONTENT
\$A9	Exponent + \$81 (\$80 if mantissa = 00)
\$AA-\$AD	Mantissa, normalized so that Bit 7 of MSB is set. \$AA is MSB, \$AD is LSB.
SAE	Sign of mantissa

A parameter passed to an assembly language subroutine from BASIC can be truncated by the subroutine to a 2-byte integer and deposited in SAC (MSB) and SAD (LSB). If the parameter is greater than 32767 or less than -32768, an FC error will result. The address of the subroutine that converts a floating-point number to an integer is located in \$B006, \$B007.

A parameter passed to BASIC from an assembly language subroutine will be converted to floating-point. The address of the subroutine that performs this conversion is in \$B008, \$B009. The integer MSB (\$AC) must be in the accumulator; the integer LSB (\$AD) must be in the Y register.

Prior to executing USR, the starting address of the assembly language subroutine must be stored in locations \$04 (LSB) and \$05 (MSB). This is generally performed using the POKE command. Note that more than one assembly language subroutine may be called from a BASIC program, by changing the starting address in \$04 and \$05.

Figure F-1 is the listing for a BASIC program that calls an assembly language subroutine located at \$A00. Here's what the BASIC program does:

- * Line 10 - Stores the starting address of the assembly language subroutine (\$A00) into locations \$04 and \$05, using POKE.
- * Line 20 - Asks for a number "N".
- * Line 30 - Calls the subroutine, with N as the parameter.
- * Line 40 - Upon return from the subroutine, the BASIC program prints X, the parameter passed from the subroutine to the BASIC program.
- * Line 50 - Loops back to get a new N

```

Figure F-1. BASIC Program That Calls Assembly Language Subroutine

The assembly language subroutine (Figure F-2) performs these operations:

- * Prints the floating-point accumulator (\$A9-\$AE), using Monitor subroutines NUMA (\$EA46), BLANK (\$E83E) and CRLF (\$E9F0),
- * Converts the floating-point accumulator to an integer, using the subroutine at \$BF00. The address \$BF00 was found in locations \$B006, \$B007. (Address \$BF00 may vary with different versions of BASIC. Be sure to check locations \$B006 and \$B007 for the correct address.)
- * After conversion, the program again prints the floating point accumulator,

- * The program then swaps the bytes of the integer.
- * Finally, the program converts the result to floating point and returns to BASIC (JMP COD3). Address SCOD3 was found in locations \$B008, \$B009. (Address SCOD3 may vary with different versions of BASIC. Be sure to check locations \$B008 and \$B009 for the correct address.)

G STORING AIM 65 BASIC PROGRAMS ON CASSETTE

AIM 65 BASIC Programs can be stored on cassette tape by using BASIC's SAVE and LOAD commands, or by using the AIM 65 Editor. Before employing either procedure be sure to carefully observe the recorder installation and operation procedures given in Section 9 of the AIM 65 User's Guide.

RECORDING ON CASSETTE USING THE BASIC SAVE COMMAND

The procedure to store a BASIC program is:

1. Install a cassette in the recorder, and manually position the tape to the program record

position. Be sure to initialise the counter at the start of the tape.

Note: Since remote control must be used to retrieve a BASIC program, observe the tape gap CAUTION in Section 9.1.5 (Step 1) of the AIM 65 User's Guide.

2. While in BASIC, type in SAVE. BASIC will respond with:

OUT=

3. Enter a T (for "Tape"). BASIC will display:

OUT=T F=

4. Enter the file name (up to five characters). If the file name is FNAME, BASIC will display:

OUT=T F=FNAME T=

5. Put the recorder into Record mode.

6. Enter the recorder number (1 or 2) and type RETURN.

7. If remote control is being used, observe the procedures outlined in Section 9.1.5 of the AIM 65 User's Guide.

8. When recording has been completed, BASIC will display the cursor.

9. Switch the recorder out of record mode.

RETRIEVING A PROGRAM FROM CASSETTE USING THE BASIC LOAD COMMAND

The procedure to retrieve a BASIC program is:

1. Install the cassette in the recorder., and manually position the tape to about five counts before the beginning of the desired file.

Note: Remote control must be used when retrieving a file via BASIC.

2. While in BASIC, type in LOAD. BASIC will respond with:

IN=

3. Enter a T (for "Tape"). BASIC will display:

IN=T F=

4. Enter the file name. If the file name is FNAME, BASIC will display:

IN=T F=FNAME T=

5. Enter the recorder number (1 or 2) and type RETURN.

6. Put the recorder into play mode. Be sure to observe the procedures outlined in Section 9.1.6 of the AIM 65 User's Guide.

While the file is being read, each line will be displayed (and printed, if the printer is on). If the printer is on, the tape gap (SA409) will probably have to be increased.

The file being loaded will not overlay any BASIC statements already entered unless the statement numbers are the same.

7. When loading has been completed. BASIC will display the cursor.

8. Switch the recorder out of play mode.

CASSETTE OPERATIONS USING THE AIM 65 EDITOR

AIM 65 BASIC programs can also be stored and retrieved from cassette using the AIM 65 Editor. However, if the program is to be retrieved by BASIC at some future time, one rule must be

observed:

When BASIC stores a program on cassette, it inserts a CTRL/Z after the last line. The AIM 65 Editor will strip off the CTRL/Z when it retrieves the program. Therefore, before storing a BASIC program from the Editor, the user must insert a CTRL/Z following the last line of the program.

H ATN IMPLEMENTATION

The ATN function (see Subject 307) can be programmed in RAM using the AIM 65 Mnemonic Entry (I) and Alter Memory Locations (/) commands, as shown below. The program is written for the AIM 65 with 4K bytes of RAM. The ATN function can be relocated elsewhere in memory by changing the starting addresses of the instructions and constants, the conditional branch addresses, the vector to the constants start address and the vector to the ATN function start address.

ATN FUNCTION CONSTANTS ENTERED BY ALTER MEMORY <M>

<M> = OF80 XX XX XX XX	Constants Starting Address = 0F80
</> = OF80 OB 76 83 83	8

BASIC INITIALIZATION FOR ATN FUNCTION

BASIC memory must be initialized below the memory allocated to the ATN function. The ATN vector in RAM must also be changed from the address of the FC error message to the starting

address of the ATN function instructions. This can be done using BASIC initialization, as follows:

```
<5>
MEMORY SIZE? 3968          Limit BASIC to F80
WI DTH?                   16
3438 BYTES FREE
AIM 65 BASIC V1.1
POKE 188, 189               Change ATN function vector low to $BD
POKE 189, 15                Change ATN function vector high to $OF
?ATN (TAN(.5))             Test case to verify proper ATN function program
                            Expected answer = .5
```

SAVING ATN OBJECT CODE ON CASSETTE

The object code for the ATN function can be saved on cassette by dumping addresses \$00BB through \$00BD (Jump instruction to ATN) and \$0F80 through \$0FEC (constants and instructions) after the function is initially loaded and verified.

The ATN function can then be loaded from cassette by executing the Monitor L command after BASIC has been initialized via the 5 command. After the ATN function has been loaded, reenter BASIC with the 6 command.
